The Supreme Court in *Davis* held that for a school district to be responsible for peer-to-peer harassment, it must “retain substantial control over the context in which the harassment occurs” and “exercise significant control over the harasser.” Usually the misconduct must occur “during school hours and on school grounds.”¹²⁷ Thus, schools have a role to play, but under federal law, they are only responsible for addressing “severe, pervasive, and objectively offensive” conduct that they are aware of that denies an equal opportunity to certain students to learn or benefit from school programs. All people of good will should work to reduce irrational societal stigmatization. Yet to cast all bigotry as “bullying” is inaccurate and not productive to that end.

“Neutrality” Policies

Commissioners Achtenberg, Castro, and many public commenters (including one witness cited from our May briefing) are critical of what they refer to as school district “neutrality” policies, though they only refer to one: the “Sexual Orientation Curriculum Policy” in Minnesota’s Anoka-Hennepin School District No. 11. They express concern that this policy discourages or prohibits teachers and administrators from talking about bullying based on sexual orientation, but the policy says nothing of the sort. The Anoka-Hennepin policy only governs what should be taught as part of the district’s official curriculum, and it specifically contemplates that staff may need to address issues relating to sexual orientation. It requires neutrality when they do so and further stresses that “it is important that staff do so in a respectful

manner that is age-appropriate, factual, and pertinent to the relevant curriculum." The policy is worth quoting in full:

It is the primary mission of the Anoka-Hennepin School District to effectively educate each of our students for success. District policies shall comply with state and federal law as well as reflect community standards. As set forth in the Equal Education Opportunity Policy, it is the School District's policy to provide equal educational opportunity and to prohibit harassment of all students. The Board is committed to providing a safe and respectful learning environment and to provide an education that respects the beliefs of all students and families.

The School District employs a diverse and talented staff committed to serving students and families from diverse backgrounds. The School District acknowledges that one aspect of that diversity regards sexual orientation. Teaching about sexual orientation is not a part of the District adopted curriculum; rather, such matters are best addressed within individual family homes, churches, or community organizations. Anoka-Hennepin staff, in the course of their professional duties, shall remain neutral on matters regarding sexual orientation including but not limited to student led discussions. If and when staff address sexual orientation, it is important that staff do so in a respectful manner that is age-appropriate, factual, and pertinent to the relevant curriculum. Staff are encouraged to take into consideration individual student needs and refer students to the appropriate social worker or licensed school counselor.

Whatever one thinks of the actual policy, it is nothing like the caricature of it that appears in the press and elsewhere.¹²⁸ The policy acknowledges the need to "prohibit harassment of all students." The district's goal is a "safe and respectful learning environment" and to respect "the beliefs of all students and families." The policy acknowledges that the diversity of students, families, and staff includes "sexual orientation." And it is not a general neutrality policy but a "curriculum" policy: extended teaching about sexual orientation is not part of the curriculum, but the district goes to some pains to explain that this policy shall not be read to cut off discussion of sexual orientation when appropriate to the regular curriculum.

The district has other policies addressing bullying and LGBT issues.¹²⁹ Its "Harassment, Violence and Discrimination Policy" notes that sexual orientation is one of the protected classifications set forth in the district's Equal Educational Opportunity Policy. The district "prohibits any form of discrimination including sex, race, religion, disability or any other protected classification [which includes sexual orientation]." It is a violation of the policy "for any student or District personnel through conduct or communication to harass; inflict, threaten to inflict or attempt to inflict violence; or discriminate against a pupil or other District personnel on the basis of sex, race, religion, disability or any other protected classifications set forth in . . . the District's Equal Educational Opportunity Policy [which includes sexual orientation]."

The district also has a comprehensive anti-bullying policy protecting all students. The district has issued anti-bullying training and support programs for staff and students, which notes that "we have a number of board policies designed to prevent harassment or bullying for any reason, including sexual orientation or gender." One of the materials provided is a power point presentation for staff, "Sexual orientation and Harassment: A Guide for Protocol and Response," "on how to respond to anti-GLBT language and harassment and how to assist students who come out." The district has a number of other GLBT-specific trainings and programs as well.

Certainly the general description of the policy by its critics seems quite mistaken. Commissioner Achtenberg also writes in her statement that the implementation of the curriculum policy was problematic, citing the plaintiffs' allegations in a lawsuit filed against the school district, among other things. That issue is still the subject of litigation,¹³⁰ so the court may determine if it was implemented in a manner inconsistent with law. Whatever the result, however, there is no support for the conclusion that all curriculum policies of this sort are problematic.

Religion

Although prohibitions on national origin discrimination may sometimes overlap with religious bigotry, discrimination based on religion is not itself banned by Title VI. We voted for a motion to amend finding number two, clarifying that ED "interprets federal civil rights laws to provide it with jurisdiction to protect students from peer-to-peer harassment that is based on the student's actual or perceived shared ancestry or ethnic identity rather than on the students' religious practices."¹³¹ Congress may want to go further than ED's interpretation and consider prohibiting all discrimination on the basis of religion in government-run schools, but it should consider the appropriate remedies for this prohibition and a number of exemptions for religious institutions if the law applies beyond government-run schools. The contours of such exemptions are difficult to draw,¹³² and the implications of additional liability in this area should be carefully weighed.

Commissioner Yaki's Statement

Commissioner Yaki argues that there is a compelling governmental interest in protecting LGBT students from bullying, which overrides students' free speech interests. His citation of Supreme Court authority for this proposition is extremely curious. We have previously explained why even the most well-settled government interests do not trump all student speech rights and justify whatever anti-discrimination or anti-harassment policy well-meaning bureaucrats dream up.¹³³

In any event, ED cannot, as Commissioner Yaki urges, withhold federal funding from schools on whatever basis it or he thinks proper while awaiting Congress to ratify that authority. Section 5 of the Fourteenth Amendment grants Congress the power to enforce the Amendment's terms, not any agency of the federal government. Sexual orientation is effectively covered under Title IX because OCR and the courts interpret sex discrimination to include discrimination based on sex stereotypes. And Title VI protects groups that have an actual or perceived shared ancestry or ethnic characteristics who also share a religion. ED can no more expand the protection for religion or add new categories than it can prohibit "lookism." It can only enforce the statutes enacted by Congress, which must be interpreted in a manner faithful to their text.

Dissenting Statement of Commissioner Gail Heriot, with Which Commissioners Peter Kirsanow and Todd Gaziano Concur

I. Background to the Report: A Twice-Told Tale Rather Than an Investigation

This report has been a disappointment—though its shortcomings can in no way be attributed to our staff. The responsibility must lie with the Commission itself. Switching topics

at the last possible moment made it impossible for the report to be anything but an uncritical re-telling of the positions of the Department of Education and the Department of Justice—along with a very brief nod to a few of the objections to those positions.¹ Nothing that can be dignified with the term "investigation" has occurred here. No useful new evidence is uncovered. No serious analysis has been engaged in.²

In the Commission's charter, Congress requires us to produce at least one report each year critiquing the manner in which a federal agency enforces civil rights laws.³ It is for that reason that the Commission is frequently referred to as a "civil rights watchdog."⁴ Our job is to be fair and independent critics.

The annual enforcement report has traditionally been the most important project the Commission undertakes in any given year. It requires research and development that usually spans a year or more. This report was put together in less than a third of the usual time. Similarly, the length of time for individual commissioners to write their statements was reduced from 30 days to seven days from the date the report was adopted.⁵

There is a backstory here: After considering several projects for several months over the summer of 2010, the Commission decided on October 8, 2010 that this year's topic would be the Department of Justice Civil Rights Division's use of the doctrine of *cy pres* in settling civil rights lawsuits brought on behalf of a class.⁶ That decision was already a little bit later in the year than usual. It was in part prompted by an article entitled *Justice Department Steers Money to Favored Groups*, which appeared in the *Washington Examiner* on August 5, 2010.⁷ The Commission set out to determine whether the concerns discussed in that article were justified.⁸ The article's author, Byron York, outlined the policy at issue this way:

The Justice Department has found a new way to pursue civil rights lawsuits, using the power of the Civil Rights Division not just to win compensation for victims of alleged discrimination but also to direct large sums of money to activist groups that are not discrimination victims and not connected to a particular suit.

In the past, when the Civil Rights Division filed suit against, say, a bank or a landlord, alleging discrimination in lending or rentals, the cases were often settled by the defendant paying a fine to the U.S. Treasury and agreeing to put aside a sum of money to compensate the alleged discrimination victims. There was then a search for those victims—people who were actually denied a loan or an apartment—who stood to be compensated. After everyone who could be found was paid, there was often money left over. That money was returned to the defendant.

Now, Attorney Eric Holder and Civil Rights Division chief Thomas Perez have a new plan. Any unspent money will not go back to the defendant but will instead go to a "qualified organization" approved by the Justice Department. And if there is not enough unspent money—that will be determined by the Department—then the defendant might be required to come up with more money to give to the "qualified organization."

The idea of directing unclaimed damage funds to non-profit groups whose interests are thought to be aligned with the unidentified victims' is superficially appealing. Advocates of *cy pres* argue that it solves the problem of under-deterrence that occurs when the victims of the defendant's wrongdoing fail to come forward and claim their share of the settlement made on their behalf.⁹ But as several respected legal scholars and practitioners have pointed out, it is also fraught with potential conflicts of interest.¹⁰ Northwestern University law professor Martin H. Redish and his co-authors have stated that the use of *cy pres* in the class action context "richly deserves" "scathing scholarly critique."¹¹

The conflicts of interest are by no means unique to civil rights cases brought by the federal government on behalf of a class of victims. They are equally significant in private class actions. But they are nevertheless important in the governmental context: When the Civil Rights Division selects a non-profit organization to benefit from the settlement of a legal dispute, how does it make that selection? Are there safeguards in place to prevent organizations that are simply the personal favorites of Civil Rights Division officials or staff members from being selected? Have any of the organizations that have been selected in the past employed family or friends of Civil Rights Division employees (or former Civil Rights Division employees themselves)? Are non-profit organizations lobbying the Civil Rights Division to be included as fund recipients (as they are already lobbying courts in connection with private class actions)?¹² Is it appropriate for Civil Rights Division attorneys to be dispensers of political patronage on such a large scale? Has the Civil Rights Division come under pressure to bring the kind of legal action that is most likely to benefit these non-profit organizations rather than the kind of legal action that would best vindicate the national interest? Does the Civil Rights Division exert less effort to locate actual victims of wrongdoing when a favored non-profit group has been selected to receive any uncollected damages? All of these questions deserve answers.

Pursuant to the Commission's decision, the Commission's staff had researched the issue, prepared a discovery plan and drafted initial sets of interrogatories, which were then served on the Department of Justice. Everything was underway. The Commission had received a partial response from the Department of Justice and was expecting the remaining documents soon. But the terms of Chairman Gerald Reynolds and Commission Ashley Taylor, Jr.—both Bush appointees—expired at the end of 2010, and in early 2011 they were replaced by Chairman Martin Castro and Commissioner Roberta Achtenberg.¹³ At its first opportunity, the newly-constituted Commission voted to abort the *cy pres* report, thus letting the Department of Justice off the hook in responding to the Commission's interrogatories. The bullying topic addressed in this report—a favorite topic of the current Administration-- was hurriedly substituted, and the Commission staff had to start from scratch.¹⁴

This looks very bad. The Byron York article in the *Washington Examiner* at least implied that the Civil Rights Division under the leadership of Obama appointees may have engaged in questionable activities. Prominent legal scholars had agreed that the use of the *cy pres* doctrine in class actions creates a serious potential for conflicts of interest. The Commission's report was designed, among other things, to allow the Division to demonstrate that its procedures are sufficient to guard against these potential conflicts of interest and that no cronyism had taken place in recent past. One would think under the circumstances the Civil Rights Division would prefer that the report be completed, rather than leave the question of conflicts of interest on its part dangling. Nevertheless, the investigation was shut down by a change in personnel on the Commission shifting the balance of power to Obama appointees.¹⁵

Meanwhile, given the late date at which the bullying topic was selected, there has been no opportunity for the Commission to root out useful new information about bullying or about the method by which the Department of Education enforces its bullying policy.¹⁶ I will therefore confine my remarks to a very general level.

II. The Federal Government is Ill-Suited to the Role of Controlling Schoolyard Bullies

Remember when children used to say “Don’t make a federal case out of it”? In those days, even fourth graders understood that not every problem is best dealt with at the federal level. These days, however, everything seems to be a federal case—even schoolyard bullies.

The point is not that bullying is unimportant. Few things are as important as ensuring that all our nation’s children can attend safe schools that are conducive to learning. But, in the absence of extraordinary circumstances, the problem can only be dealt with effectively at the local level. Individual teachers and principals backed up by active parents, school boards, school district officials, and students themselves must be in charge. It is their battle to win or lose. They are the heroes in this story, not the Department of Education.

Dealing with bullies requires knowledge of particular personalities and situations. Only their teacher knows that when little Owen doesn’t want to go out to recess, it is likely because the bigger kids—Benjamin and Elijah—have been harassing him and that he is too embarrassed to say so. Only the teacher knows that when little Chloe claims she has been bullied by her playmates, she is probably telling a tall tale, as she has done many times before. Teachers must act quickly and decisively at times, but they must also be careful and nuanced in dealing with their charges. In addition to knowing about the subjects they teach and how to teach them, they must possess the skills of both a psychologist and a police officer.

One could argue that any help in this regard should be welcome. But help from the 800-pound gorilla can be worse than no help at all. And that is what anything as large and powerful as the federal government inevitably is. The fact that it may be well-meaning is nice to know, but it shouldn’t make anyone want to trust it with a china tea set.

It is not that 800-pound gorillas are never useful. When it comes to fighting a war or building an interstate highway system, such a creature is perhaps the perfect ally.¹⁷ But helping school districts deal with discipline problems is a very different endeavor.

Local schools must do two things to satisfy the Department of Education: They must do the right thing in response to bullying motivated by race, sex, national origin or disability. Then they must be prepared to demonstrate with evidence that they have done the right thing. Sadly, in the real world, the latter task begins to overshadow the former. That is in the nature of bureaucracy. Teachers and principals must document the steps they have taken. Slowly, but unavoidably, the emphasis shifts from doing what the teacher and principal believe is the right thing to demonstrating that the school has done what the teacher and principal think some Department of Education official will think is the right thing. This is a shame. Their own judgment may have been imperfect—just like every other human being’s on the planet Earth—but it is better informed than the Department of Education’s and hence much more likely to be on target. Like every other person in a position of authority, teachers and principals may need some supervision. But it is better for that supervision to come from someone closer to the situation than from the Department of Education.

For a sense of how policies like the Department of Education’s bullying policy have worked in the past, one need only look to its very similar sexual harassment policy and the zero tolerance rules that have evolved from it:¹⁸

- Two middle school students—Cory M. and Ryan C., both 13, were arrested and charged with a *crime* at Patton Middle School in McMinnville, Oregon for slapping girls’ posteriors in an exuberant greeting in February of 2007.¹⁹

- Seven-year-old Randy C. saw another child hitting a fellow first-grader's buttocks, so he did it too at Potomac View Elementary School in Woodbridge, Maryland in February of 2009. The principal called the police on him.²⁰
- A five-year-old Hagerstown, Maryland boy was written up for sexual harassment for pinching girls' rear ends in the hallway at Lincolnshire Elementary School. Indeed, 28 kindergarteners were suspended for sex offenses, including 15 cases of sexual harassment in the 2005-2006 school year.²¹
- In December of 2006, a 4-year-old Waco, Texas boy was suspended for hugging a teacher's aide and rubbing his face in her chest.²²
- At Downey Elementary School in Brockton, Massachusetts, a 6-year-old was suspended for three days after he put two fingers inside a fellow firstgrader's waist band. He told his mother that the girl had touched him first.²³
- A 6-year-old in Greer, South Carolina was accused of sexually harassing his kindergarten teacher, because he told one of his classmates that he liked looking at her behind.²⁴
- According to the Maryland Department of Education, 166 elementary school students were suspended in the 2007-2008 school year for sexual harassment, including three pre-schoolers, 16 kindergarteners and 22 first graders. In Virginia, 255 elementary students were suspended for offensive sexual touching in that same year.²⁵

One could argue that these school districts have simply misinterpreted what the Department of Education requires. But that is no answer. It is in the nature of distant bureaucracies that their edicts will be misinterpreted. One can argue that schools shouldn't make such mistakes, but that is no more useful than King Canute's command that the tides recede. The fact is that people make fewer mistakes when they rely upon their own common sense than when they try to please some distant bureaucracy. Indeed, that is part of why it is not a good idea to make everything a federal issue.

The problem is structural. If a school district attracts the attention of the Department of Education and is forced to submit to an investigation, it is going to cost it enormous resources. Lawyers will have to be consulted, and considerable staff time will have to be devoted to dealing with an investigation. The object of the game therefore is to avoid such attention. It is natural for a school district to implement a policy that leans over backwards to avoid trouble.

A policy that leans over backwards to avoid one kind of risk will inevitably pay insufficient heed to a countervailing consideration. In the case of sexual harassment policies, young children who cannot even spell "sexual harassment" have been needlessly traumatized. Their educations have been interrupted by uncalled-for suspensions. And these well-publicized cases involving kindergartners and first graders are unlikely to show the full extent of the problem. There are likely lots of cases that are not quite as perfect for media ridicule as the tiny tot cases, but in which an injustice was nevertheless done.²⁶ In the end, the greatest casualty of the Department of Education's war may turn out to be the easy-going relations between the sexes that have been characteristic of American culture for a long time. When young people have to be careful about what they say or do around the opposite sex, the result is likely to be that they say and do less.

In the case of the bullying policy, the neglected countervailing consideration may turn out to be the First Amendment. As then-judge Samuel Alito stated in *Saxe v. State College Area School District*:²⁷

There is no categorical “harassment exception” to the First Amendment’s free speech clause.

...
There is of course no question that non-expressive, physically harassing conduct is entirely outside the ambit of the free speech clause. But there is also no question that the free speech clause protects a wide variety of speech that listeners may consider deeply offensive, including statements that impugn another’s race or national origin or that denigrate religious beliefs.

To be sure, First Amendment protections operate a little differently in school settings than they do in the marketplace. But they operate nonetheless—especially in this case, given, as Professor Eugene Volokh pointed out in his written testimony, that the Department of Education’s Dear Colleague Letter appears to cover certain off-campus speech as well as on-campus speech.²⁸ There is, however, no federal agency that actively protects students’ First Amendment rights.²⁹ As a result, the incentive is for schools to give these rights a lower priority.

Anyone who has followed higher education over the last couple of decades knows that college campuses have been home to serious controversies over First Amendment rights.³⁰ It is one of life’s crueler ironies that colleges and universities—the very institutions that should hold freedom of expression most dear—have instead led the charge against those rights.³¹ In his testimony, Professor Volokh recounted many illustrative incidents; many more could be told. The Department of Education’s Dear Colleague letter is likely to push K through 12 education a little further down the path that higher education has recently followed.³²

Bureaucratic solutions are not the answer to every problem. The power of the federal government is a tool like any tool and should be used only in the right situation. For example, more than forty years ago the Department of Health, Education and Welfare (predecessor to the current Department of Education) performed an invaluable service in conjunction with the Department of Justice in coercing recalcitrant schools districts into desegregating. It had been a decade since *Brown v. Board of Education*, and many schools were just as segregated as they had been before that decision. Armed with Titles IV and VI of the Civil Rights Act of 1964, they indeed came down on these school districts like the proverbial 800-pound gorilla. Such a solution was necessary and altogether appropriate under the circumstances.³³

This is not 1964. There is no credible evidence that any school district in the nation is pro-bully. Mistakes happen; teachers and principals have not always done the right thing.³⁴ But these mistakes are not less likely to happen with vigorous federal oversight. Indeed, I believe they are more likely to happen. Under the circumstances, a lighter touch that the Department of Education’s Dear Colleague Letter offers is called for.

III. Nothing in the Statements of the Commission Members Who Voted for the Report Justifies Making a Federal Issue Out of Schoolyard Bullying

Chairman Castro rightly states in his Statement that “each of us, regardless of our Party affiliation or our political ideology, wants to have communities and schools that are safe for our children, regardless of their race, national origin, sex, religion, disability status or sexual orientation. Where we may differ is how to accomplish that goal.”³⁵ But he draws very different conclusions from that statement than I do. To me, the fact that we all agree we want safe schools for our children means that the aggressive federal oversight represented by the Department of Education’s Dear Colleague Letter is unnecessary and will likely be counterproductive. Different school districts, indeed different teachers and principals, should take different

approaches to the problem, and they should learn from each other's successes and failures. Meanwhile, creating media events like our May 13, 2011 briefing for the sake of media events is a job that can and should be left to the politicians.³⁶

What disturbs me is the lack of real discussion in the Statements. Nowhere is an effort made to explain why the federal jurisdiction over these issues is making things better. The point is taken for granted. The Statements contain no recognition of the fact that entrusting an issue—especially an important issue—to the federal bureaucracy has costs.

I wish I could fully explain the modern tendency toward an ever-larger and more powerful centralized government. Part of it is obvious, of course: It is a one-way ratchet. Once a bureaucracy is created, it requires extraordinary political will to shrink it, and hence it hardly ever happens. As the bureaucracy grows, so too does the class of persons who service it from the outside—lobbyists, lawyers, and professional political activists. Such persons, like government employees themselves, are likely to see government action as the solution to every problem—especially when an important by-product of every new federal initiative is to provide white-collar jobs to people like them.³⁷

It is easy to overlook the structural conflicts of interest that separate lobbyists, lawyers and professional activists from the people they purport (and indeed usually in good faith are attempting) to represent. But a wise policymaker will never lose sight of those conflicts: A lawyer or lobbyist benefits from complex and ever-changing law; his clients usually benefit from clear and stable law. A professional political activist needs political victories in the form of legislation passed or favorable administrative action; without such victories he cannot raise money. It is less important that these victories ultimately actually benefit anyone, much less those who thought they would be benefited. The professional political activist surely has no interest in examining past victories to find out whether they provided the promised benefits.

The primary political organizations that have supported the Department of Education's bullying policies have been civil rights organizations specializing in the concerns of sexual minorities. Sometimes their efforts have been part of broader efforts at the local level to combat bullying, and sometimes they have been part of efforts in the national media to assure sexual minority students who feel isolated that there are lots of Americans who wish them well. I believe these very different aspects of the anti-bullying movement may run together in the minds of its supporters. But they need to be considered and evaluated separately. I question whether increased power in the hands of the Department of Education will, in the long run, be in the interest of sexual minority students in particular. If the stereotypes of sexual minority members as particularly likely to be artistic and creative are even partly true, it is not clear that a national policy of deadening bureaucracy in the schools is in their interest.³⁸

IV. Some of the Literature Cited in Commissioners' Statements and in the Report Needs at Minimum to be Put in Perspective

Given the very short period of time allocated to put together this Report (and the Commissioners' statements), it has been impossible to do anything approaching an adequate analysis of the many social science articles, advocacy pieces masquerading as social science and straight advocacy pieces cited in the Report and in the draft Statements.³⁹ Nor has there been time to canvass the literature to determine what was left out of the Report. Nevertheless, I have tried to read through a sampling of the articles cited in Commissioner Achtenberg's statement.⁴⁰ What follows are notes on some of the issues I spotted.

Bullying of Disabled Students: I have no trouble believing that some kinds of disabled students are bullied more often than other students—at least in environments where non-disabled students are left unsupervised in the presence of these disabled students. That is the nature of bullying; it is the abuse of the weak by the strong. But we should not pretend that we have useful data on in-school bullying of disabled students.

For example, Commissioner Achtenberg quotes from the Report this way:

“[i]n a 2009 study of parents of children with Asperger Syndrome, 94 percent reported that their children had been bullied. [citation omitted.] Additionally, 65 percent reported that their children had been victimized by peers within the past year, while 50 percent reported that their children were scared by their peers.”⁴¹

Actually it was a 2002 study—*Middle Class Mothers’ Perceptions of Peer and Sibling Victimization among Children with Asperger’s Syndrome and Nonverbal Learning Disorders*—that found the 94% rate.⁴² The 2009 study referenced in the Report—*Bullying of Students with Asperger Syndrome*—merely cites the 2002 study for that point.⁴³ The 94% figure is for mothers who responded more than zero to any of the following questions:

How often in the last year your child was hit by peers or siblings at home or schools or out in the community?

What is the number of times your child has been physically attacked by a gang or group of kids?

What is the number of times your child has been kicked or hurt in his/her private parts (nonsexual genital assaults)?

How many times did any kids, including sisters and brothers, pick on your child by chasing him or her, trying to scare him or her, grabbing your child’s hair or clothes, or making your child go somewhere or do something he or she did not want to (bullying)?

How often did your child “get scared, sick or feel really bad because of being called names, saying mean things, or told that they didn’t want him or her around anymore (emotional bullying)?⁴⁴

A few things are worthy of note about the 2002 study. First, the 411 families who participated in the study were not randomly selected. Rather, they were volunteers who responded to an internet invitation to the parents of a child with Asperger’s Syndrome or another nonverbal learning disorder to complete an anonymous questionnaire that would be mailed to their home. Given that they appeared to be looking around the internet for information about their child’s disorder, volunteers are probably more likely to report problems than non-volunteers.

Much more important, the study did not even purport to be limited to bullying at school. It included abuse by *siblings* or peers *in any situation*. I am forced to conclude from this that at least 6% of the Asperger’s Syndrome children studied were only children. Otherwise the figure would almost certainly have been 100% at least with the families that I am familiar with, not just with disabled children, but with all children. Schools cannot control what siblings do at home and have little control over what peers do to peers at shopping malls and street corners. Consequently, this study has little application to the issues before the Commission.

The 2009 study cited by Commissioner Achtenberg asked essentially the same questions to the parents of only 34 children who had been diagnosed with Asperger’s Syndrome. Like the

earlier study, it used a nonrandom sample. The parents had been “recruited online, in clinics and at autism conferences.”⁴⁵

The results showed high rates of incidents, though not nearly as high as in the 2002 study it is modeled after. The 2009 study found that 64% of parents report some sort of bullying or harassment and 50% said his or her child had been scared by peers or siblings. Again, this includes bullying or harassment anywhere, not just in school. In addition, 11.8% reported that the child at issue had not been invited to any other child’s birthday that year, 5.9% said that he or she was routinely chosen last or near last for sports teams and 2.9% said he or she sat alone at lunch everyday.⁴⁶

A few additional points may be also useful here:

- Asperger’s Syndrome children are sometimes characterized by aggression themselves, so insofar as they are more likely to be in the company of other Asperger’s Syndrome children, this may tend to elevate levels of violence. It is also possible that some of the incidents reported by parents were actions taken by non-Asperger’s children who, rightly or wrongly, perceived themselves to be acting in self-defense.
- Asperger’s Syndrome children are sometimes characterized by unwarranted or inappropriate fears, so the notion that 50% of these children were said to experience fear of their peers may be less informative than it appears on the surface.
- One of the most well-known characteristics of Asperger’s Syndrome children is an inability to judge nonverbal social cues—including facial expressions to voice inflections. As a result, insofar as parents are relying on their child’s report of an incident that occurred outside their field of vision, they may receive an inaccurate account of what happened.⁴⁷

The bottom line is that we have not begun to quantify how much more likely a child with Asperger’s Syndrome is to be bullied in school by other students—although it is easy to believe that they are. But even if we could quantify it, it would be insufficient to justify federal efforts to influence local bullying policy. Nothing in either of these studies shows that local authorities are not addressing the matter in the best way they know how or that more federal supervision would be a useful improvement.⁴⁸

Bullying on the Basis of the Victim’s Religion: Commissioner Achtenberg also draws our attention to two surveys by the Sikh Coalition—one in the San Francisco Bay Area in 2010 and one in New York City in 2007—on the subject of religious based discrimination. Of these, I have been able to locate and examine one—the New York City survey.

The fact that a survey had been conducted by an advocacy organization should ordinarily cause a critical reader to scrutinize it a bit more carefully than usual.⁴⁹ In this case, however, the survey does not require particularly careful scrutiny to reveal its problems.

The report has the tendentious title *Hatred in the Hallways: A Preliminary Report on Bias Against Sikh Students in New York City’s Public Schools*.⁵⁰ It reports the results of a poll of 205 Sikh children in New York, primarily in the borough of Queens (where most New York Sikhs reside). Two things are crucial to understanding the results obtained in it:

Because the report states that 77.5% of Sikh boys and 58.4% of Sikh students generally report being teased or harassed on account of their Sikh religion, the word “*teased*” must be emphasized. The Free Dictionary defines “tease” this way:

- 1) To annoy or pester; vex.
- 2) To make fun of; mock playfully.

Despite the Sikh Coalition's assertion that its findings are "shocking by any standard," it is never shocking to find that children tease each other. Children always tease each other. It would be shocking if they didn't. Indeed, all but the most humorless adults I know indulge in it now and then too. Sometimes children take it too far; indeed, sometimes adults take it too far. But there is nothing in the report to separate friendly but impish teasing from something worthy of discipline, much less worthy of federal intervention. There may well be a problem, but this report has not uncovered it.

It should also be noted that unlike the authors of some of the other studies cited in the Report, the Sikh Coalition evidently interviewed a number of quite young students.⁵¹ That puts the report's finding that "[t]wo out of five Sikh children who wear turbans or *patkas* [religious head coverings for younger boys] are physically harassed—beaten or touched on the head"—in a different light. Beaten or touched on the head does not mean beaten. Among the younger children, I would expect the number who have been "touched" to be extremely high. Younger children touch each other. They roll in the grass with each other, they blow spit balls at each other, and they put chewing gum in each other's hair. They are especially likely to want to touch a schoolmate if they see something that in their ignorance appears to be a funny hat. Children's ignorance, with proper treatment, goes away. Federal bureaucracies created to solve a problem that is best solved locally do not.⁵²

I am confident that the Sikh Coalition is correct that some Sikh children have been harassed on account of some other children's misperceptions that they are terrorists.⁵³ In that respect the survey may provide a useful reminder for teachers, guidance counsellors and principals: Children can be ignorant hellions. They need to be taught (1) Sikhs are not Muslims; and (2) Even if they were Muslims, that does not make them terrorists. A good course in world religions would work wonders on both counts, and it is likely to be quite a bit more effective than federal laws that require more training for teachers on how to prevent harassment.

Unfortunately, there is one more point that needs to be put out in the open with regard to *Hatred in the Hallways*. When the Sikh Coalition undertook the study (along with a similar study of adult Sikhs), it placed a promotional video on the internet explaining the motives and methods for conducting the survey. In that video, Mehtab Kaur, who is identified as a community advocate with the Sikh Coalition, states that the purpose of the survey was "to get statistics to approach government agencies and say, you know, X number of people in our community have experienced this, or you know, 45 out of 50 students surveyed say that have problems with discrimination and bullying at New York City schools. Let's do something."⁵⁴ But then she said something disturbing: "While administering the survey on Survey Day, I think most of us were surprised by the fact that, you know, some people said they hadn't experienced any discrimination and but when pressed further, you know, we—uh—one of the questions in the survey asks, 'Has anyone ever called you bin Laden or a terrorist?' and people had become so used to being called, you know, such derogatory names that they didn't really consider it harassment anymore."⁵⁵

It is hard to avoid the conclusion that Ms. Kaur is not opposed to coaching survey subjects. She seems to believe that if the survey subject tells you that he or she hasn't been discriminated against or hasn't been bullied, the thing to do is press further. Under the circumstances, relying on such a survey seems inappropriate.⁵⁶

Bullying on the Basis of the Victim's Sex: Commissioner Achtenberg's Statement points out that "a 2001 study ... found that 81 percent of students in grades 8 to 11 reported experiencing sexual harassment, including 83 percent of girls and 79 percent of boys."⁵⁷

This too needs to be put into perspective. Only about 14% of students said that there is "a lot" of sexual harassment going on in their school. Almost as many—9%—said that there was not any.⁵⁸ Overwhelmingly, students answered "Some but not a lot" or "Only a little."

Students were given the following broad definition of harassment: "Sexual harassment is unwanted and unwelcome sexual behavior that interferes with your life. Sexual harassment is not behaviors that you like or want (for example wanted kissing, touching or flirting)." Examples given to students included "Made sexual comments, jokes, gestures, or looks," "Spread sexual rumors about you," "Flashed or 'mooned' you," and "Said you were gay or lesbian" and "Wrote sexual messages/graffiti about you on bathroom walls, in locker rooms, etc." The categories that drew the most affirmative responses were "made sexual comments, jokes, gestures, or looks (71%)," "Spread sexual rumors about them (61%)," and "Said they were gay or lesbian" (61%).

Students were also invited to define sexual harassment themselves. Among the responses they gave were the extraordinarily broad "Any unwanted attention," "When someone invades your personal body space or privacy," and "Someone making advances towards me and saying things that make me feel very uncomfortable." A few students seemed exasperated with the concept: "Feminist-politically correct language for saying things like 'hello good-looking.'"

For a sense of how important the students themselves regarded this conduct, one may look at how they responded to the particular harassment they experienced. Only 20% of students said they had told a teacher or other school employee about an incident of sexual harassment.⁵⁹ The study produced the following list of responses to the question, "Why didn't you tell anyone?" I quote the list in the study in full:

Boys

"I don't know. Thought it was normal kid stuff." (eighth-grader) "Because I didn't really care, it was not a big deal." (ninth-grader)

"Because I'm a guy and I don't care. I'm not so insecure that someone saying I'm gay is gonna bother me. I'm not, so who cares?" (ninth-grader)

"I could handle it myself." (11th-grader)

Girls

"I don't know. I just didn't feel it necessary." (ninth-grader) "I liked it." (10th-grader).

"... make a mountain out of a molehill. I handled the situation myself, or then eventually went away)." (10th-grader)

"I didn't want to be a tattletale." (11th-grader)

"It wasn't anything that bothered me, and I knew that it would stop. And it did." (11th-grader)⁶⁰

This study was clearly written to highlight sexual harassment as a serious issue. If the study's authors had received more troubling answers to the question of why a student had failed to draw a harassment incident to the attention of a teacher or other school official—such as "I was afraid to"—it is unthinkable that they would have failed to report it.

In the end, this study proves neither that further federal action is needed nor that past federal action has produced beneficial results.

Bullying on the Basis of the Victim's Race: In her Statement, Commissioner Achtenberg quotes from the Report's discussion of the California Healthy Kids Survey for her belief that "[u]p to one-quarter of racial and ethnic minority students are targeted for peer-to-peer bullying, harassment, and violence:

"[t]he California Healthy Kids Survey conducted in 2007-2009 found that when youth in California were bullied or harassed on school property, the most common specific reason cited was because of their race or national origin, with about 18 percent of students in grades 7, 9, and 11 reporting at least one bullying incident in the past year for this reason. ... When results for 9th and 11th grade students are broken down by race and ethnicity, African-American students reported being bullied or harassed due to their race or ethnicity at the highest rate—23 percent. Twenty-two percent of Asian-American students, 22 percent of Native Hawaiian or Pacific Islanders students and 20 percent of Native American students reported being harassed due to their race, ethnicity, or national origin as well."

I should add the rate for non-Hispanic white students was 13% and for Hispanic or Latino/Latina students it was 17%.

All these figures can be somewhat misleading. It is not always possible to know why one is being harassed or bullied.⁶¹ A certain number of times an individual will surmise from the circumstances that he is being targeted on account of his race given that the bully/harasser is of another race, and a certain number of times he will be wrong. If all encounters with bullies and harassers were random and none were racially motivated, members of racial minorities may nonetheless more frequently conclude that they have been racially targeted simply because a larger percentage of their encounters with bullies or harassers will be with members of another race.

A useful check on the conclusion that African Americans and Asians are more likely to be the target of racially motivated bullying than whites or Hispanics is the Health Behaviour of School-Aged Children survey. In "Bullying Behaviors Among US Youth: Prevalence and Association with Psychosocial Adjustment," Dr. Tonjah Nansel et al. analyzed the data collected in that massive survey and found that black students report that they have been bullied *less* often than white or Hispanic students.⁶² Their research showed that 29.9 percent of black students reported that they had been bullied during the current school term; in contrast 43.7 percent of white students reported bullying. The figure for Hispanics is 40.6 percent; no figures were given for other races.⁶³ To be sure, these figures are for bullying of any kind, not specifically for bullying based on race or ethnicity. Still, it would be odd to find that while black students are subjected to more bullying based on race or ethnicity, they were correspondingly bullied so much less on other bases that it nets out in favour of less bullying overall.

The HBSC also sheds useful light on the CHKS's finding that "the most common specific reason cited" for bullying is "race or national origin."⁶⁴ In fact, the CHKS only asked about what it calls "Hate-Crimes Reasons" for bullying—"race, ethnicity or national origin," "religion," "gender," "sexual orientation," and "physical/mental disability." In contrast, the HBSC asked students whether they had been "belittled about religion or race," "belittled about looks or speech," "subjects of rumors," or "subjects of sexual comments or gestures."

Not surprisingly to anyone who has attended high school, "belittled about looks or speech" came in first, followed closely by "subjects of rumors." "Belittled about religion or race" was

not just last, it was dead last. All the other categories were more than twice as common.⁶⁵ This is not to suggest that bullying on the basis of race or ethnicity is not deserving of attention by teachers and principals. It simply needs to be seen in context. Also not surprisingly, the serious differences in bullying levels were not between races, but between genders and age groups. While females are more likely to be the subject of "sexual comments or gestures," males are much more likely to be "hit, slapped or pushed." Sixth graders are about three times more likely to report being bullied on a weekly basis than 10th graders. A full majority of 6th graders report having been bullied in one way or another; by 10th grade that number is very nearly cut in half.⁶⁶ This latter fact is actually good news. It shows that eventually the lessons of civility are learned by most students, though not as early as might be hoped for. It does indeed get better.⁶⁷

Bullying Based on the Victim's Sexual Orientation: Everyone agrees that "[c]ompared with students who are not sexual minorities, a disproportionate number of sexual minority students engage in a wide range of health-risk behaviors."⁶⁸ For example, according to the Center for Disease Control and Prevention, approximately 6.4% of self-identified heterosexual high school students report that they have attempted suicide, while 25.8% of self-identified gay or lesbian high school students have and 28.0% of self-identified bisexual high school students.⁶⁹

The tendency to engage in high-risk behaviors is not confined to suicide attempts. According to the Center for Disease Control and Prevention, about 7.6% of heterosexual students report smoking cigarettes daily, while 23.4% of gay or lesbian students and 24.8% of bisexual students do.⁷⁰ Similarly, 4.3% of heterosexual students report that they currently drink alcohol on school property, while much larger numbers of gay or lesbian students and bisexual students do—11.8% and 13.8% respectively.⁷¹ Drug use figures are similarly skewed.⁷²

This tendency includes activity that one would not necessarily associate with troubled youth. Only about 12.3% of heterosexual high school students report that they rarely or never wear a seatbelt when riding in a car with someone else. By contrast, the figures for gay or lesbian students and for bisexual students were 21.0% and 20.4% respectively. Nevertheless, the Center for Disease Control and Prevention data do not show that gay or lesbian and bisexual youth always score higher on unsafe behaviors than heterosexual youth. Among gay or lesbian students, 22.5% and among bisexual students 16.5% reported eating vegetables three or more times a day. The figure for heterosexual students was only 11.3%.⁷³

Commissioner Achtenberg argues that "the extra pressure created by structural stigma is responsible for such disparate outcomes to the extent that they appear to exist."⁷⁴ She defines "structural stigma" to mean "the collective process by which majority class members give permission to the society as a whole to victimize minority class members."⁷⁵

It is perfectly plausible that the increased victimization can lead to an increase in what social scientists like to call (with bureaucratic blandness) "negative outcomes." But there is no way to draw the conclusion that increased victimization is the sole or even a primary cause of the increased tendency towards self-destructive conduct based on the available evidence. One simply has to take it on faith.⁷⁶

For one thing, there are many groups with high rates of suicide whose behavior is unlikely to be the result of external victimization or social stigma. According to data from the World Health Organization, Lithuania, South Korea, Kazakhstan, Belarus, Japan and Russia were the top nations for suicide. The United States ranked 39th with a rate of suicide roughly one third of Lithuania's. Jamaica has one of the lowest suicide rates in the world. Yet somebody is victimizing somebody there; it has one of the highest murder rates.

In the United States, the Centers for Disease Control and Prevention report that American Indians/Alaska natives have the highest rates of suicide. They are followed closely by non-Hispanic whites. Other races and ethnicities—Asians/Pacific Islanders, Hispanics and non-Hispanic blacks—were a distant third, fourth or fifth.⁷⁷ Although obese persons receive far more than their share of bullying, social stigma and victimization and have high rates of depression, suicide rates among them are very low.⁷⁸

There have been efforts to prove that the high risk behavior of gay, lesbian and bisexual students is the result of victimization of one sort or another. But research that is said to prove it is usually measuring something quite different from what advocates suppose. And even when most people can agree on what is being measured, causation cannot be established. Consider, for example, *Family Rejection as a Predictor of Negative Health Outcomes in White and Latino Lesbian, Gay and Bisexual Young Adults*, a 2009 study by Caitlin Ryan, David Huebner, Rafael M. Diaz and Jorge Sanchez.⁷⁹ In it, the authors argue that they have established "a clear link between specific parental and caregiver rejecting behavior and negative health problems in young lesbian, gay and bisexual adults."⁸⁰ But are the authors measuring actual rejection or just perceptions of rejection? In the study, 224 white and Latino gay, lesbian and bisexual young adults were asked to recall whether their parents or caregivers blamed them for any anti-gay mistreatment they might have suffered, how often their parents or caregivers made disparaging remarks about gays, lesbians or bisexuals and how often they were excluded from family activities, and similar questions.

The authors found that those with higher family rejection scores tended to have higher rates of suicidal ideation and of attempted suicide, higher rates of drug use and higher rates of unprotected sex.⁸¹ But are they really finding an association between family rejection and (for example) depression? Or are they finding that depressed people are more likely to remember, believe or report that they suffered rejection? Even if the reports of all 224 participants were 100% accurate, were the parents excluding them from family activities because of their sexual orientation? Or was it because of their illegal drug use, depression or suicide attempts?

Perhaps one day we will have better insight into what causes high-risk conduct among gay, lesbian and bisexual teenagers. But we need not wait for that day to ensure that their rights and the rights of all students are respected in the schools. In my opinion, the best way to do that is allow teachers, principals and local school districts to do their jobs. Nothing in this Report has persuaded me otherwise.

Statement of Commissioner Michael Yaki

The U.S. Commission on Civil Rights, historically, has never shied away from tackling controversial issues in support of civil rights. Our historic reports on civil and voting rights in the South in the early 60s became the predicate for the Civil Rights Act of 1964 and the Voting Rights Act of 1965. Through extensive interviews, hearings, and testimony both voluntary and compelled, little doubt was left that discrimination wildly at variance with Constitutional principles and protections needed to be remedied, sooner rather than later, and aggressively rather than tepidly as had been done in the past.

This Report had the potential to join the pantheon of exalted papers of the past. Unfortunately, due to a series of circumstances both beyond and within our control, it failed. The rushed timeline, the inability to thoroughly scour the literature and, most egregiously, the

absence of a rigorously constructed and sound legal theory doomed this exercise from the start. And while I voted in favor of the report, it was only to validate the one, truly, groundbreaking aspect – that this Report was the Commission's first real foray into the experiences of people who have been defined solely by their sexual orientation.¹

Nevertheless, the Commission's failure to tackle head-on the continued discrimination against Americans who are gay, lesbian, bisexual or transgender in a meaningful way that utilizes extant Constitutional doctrine is the greatest omission of this Report. I believe that in the context of the issues brought before us, First Amendment doctrine has less application to the context of school bullying when it is balanced against a countervailing principle of protecting a suspect class – in this case, youth who identify or are identified as LGTB.

In cases before the U.S. Supreme Court, the particular vulnerabilities of children have vaulted them into a special status worthy of a strong government interest. Whether the case of *Prince v. Massachusetts*, 321 U.S. 158 (1944), *Jacobsen v. Massachusetts*, 197 U.S. 11 (1905), or more recently the treatment of juvenile offenders in *Roper v. Simmons*, 543 U.S. 551 (2005), the Courts have long held that children have a different place in the application of Constitutional doctrine.

In both *Prince* and *Jacobsen*, a parents' assertion of Free Exercise principles was found to not withstand a compelling government interest in laws designed to protect children. In *Roper*, Justice Kennedy's opinion for the Court explicitly embraced social science research on the adolescents as a reason for exempting youth from the application of the death penalty and providing them the application of the Eighth Amendment proscription against cruel and unusual punishment.

"Three general differences between juveniles under 18 and adults demonstrate that juvenile offenders cannot with reliability be classified among the worst offenders. First, as any parent knows and as the scientific and sociological studies respondent and his amici cite tend to confirm, "[a] lack of maturity and an underdeveloped sense of responsibility are found in youth more often than in adults and are more understandable among the young. These qualities often result in impetuous and ill-considered actions and decisions." Johnson, *supra*, at 367; see also Eddings, *supra*, at 115–116 ("Even the normal 16-year-old customarily lacks the maturity of an adult"). It has been noted that "adolescents are overrepresented statistically in virtually every category of reckless behavior." Arnett, *Reckless Behavior in Adolescence: A Developmental Perspective*, 12 *Developmental Review* 339 (1992). In recognition of the comparative immaturity and irresponsibility of juveniles, almost every State prohibits those under 18 years of age from voting, serving on juries, or marrying without parental consent. See Appendixes B–D, *infra*.

The second area of difference is that juveniles are more vulnerable or susceptible to negative influences and outside pressures, including peer pressure. Eddings, *supra*, at 115 ("[Y]outh is more than a chronological fact. It is a time and condition of life when a person may be most susceptible to influence and to psychological damage"). This is explained in part by the prevailing circumstance that juveniles have less control, or less experience with control, over their own environment. See Steinberg & Scott, *Less Guilty by Reason of Adolescence: Developmental Immaturity, Diminished Responsibility, and the Juvenile Death Penalty*, 58 *Am. Psychologist* 1009, 1014 (2003) (hereinafter Steinberg & Scott) ("[A]s legal minors, [juveniles] lack the freedom that adults have to extricate themselves from a criminogenic setting").

The third broad difference is that the character of a juvenile is not as well formed as that of an adult. The personality traits of juveniles are more transitory, less fixed. See generally E. Erikson, *Identity: Youth and Crisis* (1968).

Finally, and perhaps most fittingly, the most famous application of the unique nature of children in Constitutional doctrine was, not surprisingly, found in *Brown v. Board of Education*, 347 U.S. 483 (1954). The Court rejected its early holding in *Plessy v. Ferguson*, 163 U.S. 537 (1896) in part, because the notion of “separate but equal” was found to have deleterious effects on black children. The Court stated:

“Segregation of white and colored children in public schools has a detrimental effect upon the colored children. The impact is greater when it has the sanction of the law, for the policy of separating the races is usually interpreted as denoting the inferiority of the negro group. A sense of inferiority affects the motivation of a child to learn. Segregation with the sanction of law, therefore, has a tendency to [retard] the educational and mental development of negro children and to deprive them of some of the benefits they would receive in a racial[ly] integrated school system...”

In so finding, the *Brown* Court in footnote 11 cited a wealth of social science studies to buttress its claim.

Taken together, these cases argue strongly that government action to stop bullying in schools, particularly bullying against LGTB or LGTB-identified children, be given substantial deference with regard to competing First Amendment concerns. Substantial evidence was introduced showing the harm suffered by LGTB or LGTB-identified children as a result of bullying. Substantial evidence was introduced showing that LGTB and LGTB-identified children are targeted for bullying and harassment.

This evidence, coupled with the unfortunate plethora of historical documented discrimination against the LGTB community, should end any debate over whether the Federal government can enact laws protecting LGTB children pursuant to its mandate under Section 5 the 14th Amendment.² While awaiting Congressional action, and rather than twist itself into knots with “Dear Colleague” letters and stretching for jurisdiction under Title IX, the Department of Education should offer emphatic guidance or stringent rulemaking that any K-12 institution receiving federal funds must provide strict protections against bullying based on race, gender, national origin, disability, religion and sexual orientation or perceived sexual orientation. These protections must be uniform, must be enforced, and have provisions for clear documentation and categorization.

End Notes

Minority stress stems from social disadvantages related to structural stigma, prejudice, and discrimination.”) (emphasis in original); cf. *Nuxoll v. Indian Prairie Sch. Dist. #204*, 523 F.3d 668, 671 (7th Cir. 2008) (Posner, J.) (“People are easily upset by comments about their race, sex, etc., including their sexual orientation, because for most people these are major components of their personal identity—none more so than a sexual orientation that deviates from the norm. Such comments can strike a person at the core of his being.”); *Wisconsin v. Mitchell*, 508 U.S. 476, 487-88 (1993) (“[T]he ... statute singles out for enhancement bias-inspired conduct because this conduct is thought to inflict greater individual and societal harm. For example, according to the State and its amici, bias-motivated crimes are more likely to provoke retaliatory crimes, inflict distinct emotional harms on their victims, and incite community unrest. ... The State’s desire to redress these perceived harms provides an adequate explanation for its penalty-enhancement provision over and above mere disagreement with offenders’ beliefs and biases. As Blackstone said long ago, ‘it is but reasonable that among crimes of different natures those should be most severely punished, which are the most destructive of public safety and happiness.’”) (Rehnquist, C.J.) (citations omitted).

⁸⁹ Friedman Comment, *supra* note 83, at 2.

⁹⁰ See Herek Statement, *supra* note 74, at 20-21 ("Although bullying and victimization have negative consequences for all students who experience them, being targeted for bullying because of one's sexual orientation is associated with more problems and greater distress than is experiencing bullying or harassment that is not related to one's identity."); *id.* at 20 ("Several studies have found that experiences with harassment and victimization based on sexual orientation account for much or all of the disparities between heterosexual and nonheterosexual students in mental health, substance use, truancy and poor school performance, and risk behaviors."); Meyer Statement, *supra* note 30, at 10 ("By definition, minority stress is unique, in that it affects and requires special adaptation by LGB people but not by heterosexuals. Therefore, minority stress confers a unique risk for diseases that are caused by stressed."); CAL. safe place, *supra* note 33, at 11 ("[O]utcomes associated with harassment based on actual or perceived sexual orientation are much more severe than outcomes associated with other harassment and bullying not based on race/ethnicity/national origin, religion, gender, sexual orientation, or disability."); see also Herek Statement, *supra* note 74, at 14 ("Research indicates that experiencing stigma and discrimination is associated with heightened psychological distress—both among gay and lesbian adults and adolescents. Being the target of extreme enactments of stigma, such as antigay criminal assault, is accompanied by greater psychological distress than is experiencing a similar crime not based on one's sexual orientation."); Meyer Statement, *supra* note 30, at 12 ("Hate crimes—perpetrated by family or strangers—are a particularly painful type of prejudice event because they inflict not only the pain of the assault itself, but also the pain associated with the social disapproval of the victim's stigmatized social group. ... Such victimization affects the victim's mental health because it damages his or her sense of justice and order.").

⁹¹ See IOM Study, *supra* note 83, at 146-47 ("It is important to note that LGBT youth are typically well adjusted and mentally healthy. Research based on probability samples with LGB youth consistently indicates that the majority

do not report mental health problems. Regarding transgender youth, although no data from national probability samples are available, studies with sizable convenience samples indicate that many, if not most, of those youth do not report mental health problems.") (citations omitted); Herek Statement, *supra* note 74, at 6-9 (describing homosexuality as a normal expression of human sexuality); Public Comment of Gay & Lesbian Alliance Against Defamation (GLAAD), at 4, May 3, 2011, *available at* <http://www.eusccr.com/GLAAD.pdf> (last visited on Sept. 15, 2011) [hereinafter GLAAD Comment] ("Research by leading psychologists has shown that individuals who identify as gay or lesbian do not have any inherent pre-existing conditions or factors that lead to depression and psychological stress, but rather the psychological stress is a direct result of, inter alia, negative societal messages.").

⁹² See, e.g., IOM STUDY, *supra* note 83, at 158 ("The experiences [with harassment, victimization, and violence] are related to increased substance abuse, mental health problems, and sexual risk-taking behavior.") (citation omitted).

⁹³ See CAL. SAFE PLACE, *supra* note 33, at 9 (analyzing data from the 2001-2002 California Healthy Kids Survey); see also Herek Statement, *supra* note 74, at 20.

⁹⁴ See CAL. SAFE PLACE, *supra* note 33, at 9.

⁹⁵ See GLSEN 2009 SCHOOL CLIMATE SURVEY, *supra* note 75, at 48; Byard Statement, *supra* note 73, at 5-6; Meyer Statement, *supra* note 30, at 14 ("Considering the chronic exposure to prejudice, discrimination, and violence at schools, is [sic] not surprising...that such anxiety, and the vigilance required because of expectation for harm, is responsible for the poorer academic performance and truancy of LGBT youth") (citations omitted).

⁹⁶ See CAL. SAFE PLACE, *supra* note 33, at 8-9 (finding that students harassed based on actual or perceived sexual orientation are three times as likely to "seriously consider" suicide and more than three times as likely to "make a plan for attempting suicide"); see also Herek Statement, *supra* note 74, at 20; Public Comment of Caitlin C. Ryan, Dir., Family Acceptance Project, S.F. State Univ., at 1-2, May 23, 2011, *available at* <http://familyproject.sfsu.edu/files/Gender%20&%20School%20Victimization%20rel.pdf> (last visited Sept. 9, 2011) [hereinafter Ryan Comment].

⁹⁷ See Anthony R. D'Augelli et al., *Suicide Patterns and Sexual Orientation—Related Factors Among Lesbian, Gay and Bisexual Youths*, 31 SUICIDE & LIFE THREATENING BEHAVIOR 250, 261 (2001), *available at* <http://www.hhdev.psu.edu/hdfs/faculty/pubs/DAugelliSLTB01.pdf> (last visited Feb. 18, 2011) (concluding that 35 percent of gay, lesbian and bisexual youth have attempted suicide at least once); Mass. Comm'n on Gay, Lesbian, Bisexual & Transgender Youth, *Massachusetts High School Students and Sexual Orientation: Results of the 2009 Youth Risk Behavior Survey*, <http://www.mass.gov/cgly/YRBS09Factsheet.pdf> (last visited May 10, 2011) (finding that gay, lesbian, and bisexual high school students are 4.4 times more likely to attempt suicide than their heterosexual peers); see also Meyer Statement, *supra* note 30, at 22 ("Minority stress is also associated with a higher incidence of suicide attempts among LGB compared with heterosexual individuals. ... This increase in suicidality is mostly related to minority stress encountered by youth due to coming out conflicts with family and community.") (citations omitted).

⁹⁸ See IOM STUDY, *supra* note 83, at 147:

Over the past decade, an increasing number of studies based on large probability samples have consistently found that LGB youth and youth who report same-sex romantic attraction are at increased risk of suicidal ideation and attempts, as well as depressive symptoms, in comparison with their heterosexual counterparts. These include both school-based, state-based and national studies. The results of these studies suggest increased rates of suicidal ideation and attempts among LGB youth in comparison with heterosexual youth even after controlling for potentially confounding factors such as substance abuse and depression. (citations omitted).

But see Kenneth M. Cohen & Ritch C. Savin-Williams, *The Positive Lives of Gay Teens*, Pa. Psychological Ass'n, Psychological News You Can Use (Dec. 2010):

[F]actors other than same-sex attractions place youth at risk for mental health problems. Chief among them is transgressing gender boundaries in behavior and interests. Gender nonconformity is the impetus for verbal and physical harassment meted out by a small number of bullies who often attack peers, regardless of sexuality, who appear unduly feminine (boys) or masculine (girls).

⁹⁹ See Statement of Tammy Aaberg at 8, May 13, 2011, *available at* <http://www.eusccr.com/19-1%20Tammy%20Aaberg.%20Parent.pdf> (last visited June 23, 2011) [hereinafter Aaberg Statement] ("These children are dead. My son is dead. ... All of these children, and too many others across the country, all died too young as a result of bullying and harassment and will be forever missed by their friends and families."); *id.* at 5 ("Students tell me that everything starts to weigh down on you and things pile up until eventually it becomes too much and you want the pain to end, so many start considering suicide as they believe it will save them and their loved ones the pain life brings them or they feel they have no hope of things ever getting better for them.");

Public Comment of Wendy Walsh at 2, Apr. 25, 2011, *available at* <http://www.eusccr.com/Walsh,%20Wendy.pdf> (last visited Sept. 15, 2011) ("I can't bring my son back. ... No mother should ever have to lose their 13-year-old child to intolerance and anti-gay harassment, especially in a place that should be providing them with an education and putting them on a path to a promising future."); Public Comment of Rep. Keith Ellison, U.S. House of Representatives, at 1, Apr. 27, 2011, *available at* <http://www.eusccr.com/29.%20U.S.%20Rep.%20Keith%20Ellison.pdf> (last visited June 23, 2011) [hereinafter Ellison Comment] ("Nine enrolled or recently graduated middle and high school students [in a single school district in Minnesota] committed suicide in 2010, including three who were gay or lesbian.").

¹⁰⁰ See Herek Statement, *supra* note 74, at 21 ("The negative psychological effects of bullying and peer victimization appear to last after students leave high school. In a study of sexual and gender minority young adults (21-25 years old), experiencing school victimization during the teen years was associated with higher current levels of depression, more suicidal thoughts, lower self-esteem, and less life satisfaction."); Ryan Comment, *supra* note 96, at 2 ("We found that ... LGBT young adults who reported high levels of LGBT school victimization during adolescence were 5.6 times more likely to report having attempted suicide, 5.6 times more likely to report a suicide attempt that required medical care, 2.6 times more likely to report clinical levels of depression, and more than twice as likely to have been diagnosed with a sexually transmitted disease and to report risk for HIV infection, compared with peers who reported low levels of school victimization.").

¹⁰¹ See Sabrina Holcomb, Muslims in America: When Bullying Meets Religion, <http://www.nea.org/home/42528.htm> (last visited May 6, 2011) (citing reports that bullying of Muslim students has increased since the September 11 terrorist attacks).

¹⁰² Ikimulisa Livingston & Leonard Greene, *Terrorized for Being a Muslim*, N.Y. POST, Oct. 12, 2010, *available at* http://www.nypost.com/p/news/local/staten_island/terrorized_for_being_muslim_8rQSU8Z5ibbMOeJnDGfOrO (last visited May 8, 2011). The student reported being kicked in the head and the groin until he bled. *See id.*

¹⁰³ *Id.*; see also Statement of Kenneth L. Marcus, Exec. V.P. & Dir. of the Anti-Semitism Initiative, Inst. for Jewish & Cmty. Research, at 4, May 13, 2011, *available at* <http://www.eusccr.com/15.%20Kenneth%20L.%20Marcus,%20Institute%20for%20Jewish%20&%20Community%20Research.pdf> (last visited June 23, 2011) [hereinafter Marcus Statement]; Holcomb, *supra* note 101 ("The dimension that makes the bullying of Muslim students particularly disturbing centers around the open prejudices and fears of adults, giving the green light to non-Muslim children that it's okay—even patriotic—to discriminate").

¹⁰⁴ See Statement of Rajdeep Singh, Dir. of Law & Policy, Sikh Coalition, at 1, May 13, 2011, <http://www.eusccr.com/17.RajdeepSingh,SikhCoalition.pdf> (last visited June 23, 2011) [hereinafter Singh Statement] ("Although the Sikh turban is a symbol of nobility and signifies a commitment to upholding freedom, justice, and dignity for all people, the physical appearance of a Sikh is often ignorantly conflated with images of foreign terrorists, some of whom also wear turbans and many of whom have received copious publicity in our mainstream media in the post-9/11 environment."). In an incident described to the Commission, a Sikh boy from the San Francisco Bay Area was called "diaper head" from the first grade; in middle school he was "called names, pushed, shoved, beaten up, had his books stolen, [turban] ripped off, lockers broken, and the day before his class final, his folder was stolen." *Id.* at 2.

¹¹² See Kenneth L. Marcus, Deputy Asst. Sec'y for Enforcement, Delegated the Authority of the Asst. Sec'y for Civil Rights, U.S. Dep't of Educ., Dear Colleague Letter: Title VI and Title IX Religious Discrimination in Schools and Colleges, Sept. 13, 2004, *available at* <http://www2.ed.gov/about/offices/list/ocr/religiousrights2004.html>

(last visited May 8, 2011) ("OCR has recently encountered allegations of racial and sex discrimination, commingled with aspects of religious discrimination against Christian students.").

¹¹³ In addition to these statutes, OCR also enforces the Age Discrimination Act of 1975, 42 U.S.C. § 6101 *et seq.* (2006), and the Boy Scouts of America Equal Access Act, 20 U.S.C. § 7905 (2006); DOJ also enforces Title IV of the Civil Rights Act of 1964, 42 U.S.C. § 2000c *et seq.* (2006), and the Equal Educational Opportunities Act of 1974, 20 U.S.C. § 1703 (2006), and it may intervene in private suits alleging violations of anti-discrimination statutes and/or the Fourteenth Amendment to the U.S. Constitution. When enforcing Title IV, which protects against discrimination based on race, color, religion, sex, or national origin, DOJ interprets that title to be consistent with case law under Title VI and Title IX, and thus applies the same legal standards under Title IV as it does under the those titles.

¹¹⁴ For further information regarding the legal standards used by ED and DOJ, see *infra* pp. 28-42.

¹¹⁵ 20 U.S.C. § 1681(a) (2006) ("No person in the United States shall, on the basis of sex, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any education program or activity receiving Federal financial assistance"); see also *id.* at § 1681(c) ("For purposes of this Chapter an educational institution means any public or private preschool, elementary, or secondary school, or any institution of vocational, professional, or higher education"). For a discussion of federal enforcement efforts under Title IX involving students who are targeted in part due to their sexual orientation or gender identity, see Section Six.

¹¹⁶ *Id.* § 1682.

¹¹⁷ See *Franklin v. Gwinnett County Pub. Sch.*, 503 U.S. 60, 75-76 (1992).

¹¹⁸ *Id.* at 75. ("Unquestionably, Title IX places on [schools] the duty not to discriminate on the basis of sex, and 'when a supervisor sexually harasses a subordinate because of the subordinate's sex, that supervisor "discriminate[s]" on the basis of sex.' We believe the same rule should apply when a teacher sexually harasses and abuses a student.") (quoting *Meritor Sav. Bank, FSB v. Vinson*, 477 U.S. 57, 64 (1986)).

¹¹⁹ *Davis v. Monroe County Bd. of Educ.*, 526 U.S. 629, 650 (1999) ("[S]tudent-on-student sexual harassment, if sufficiently severe, can . . . rise to the level of discrimination actionable under [Title IX].").

¹²⁰ See, e.g., *J.K. v. Ariz. Bd. of Regents*, No. CV 06-916-PHX-MHM, 2008 WL 4446712 at *12 (D. Ariz. Sept. 30, 2008) (citing *Soper v. Hoben*, 195 F.3d 845, 855 (6th Cir. 1999)) (holding that rape of plaintiff constituted "severe, pervasive, and objectively offensive" sexual harassment); *Kelly v. Yale Univ.*, No. Civ. A. 3:01-CV-1591, 2003 WL 1563424, at *3 (D. Conn. Mar. 26, 2003) ("There is no question that a rape ... constitutes severe and objectively offensive sexual harassment ..."); *S.S. v. Alexander*, 177 P.3d 724, 741 (Wash. Ct. App. 2008) (stating that "[i]n the Title IX context, there is no 'one free rape' rule").

¹²¹ See *Price Waterhouse v. Hopkins*, 490 U.S. 228 (1989), *superseded by statute on other grounds* (holding that sex-stereotyping is actionable under Title VII); see also, e.g., *Doe v. Brimfield Grade Sch.*, 552 F. Supp. 2d 816, 823 (C.D. Ill. 2008) ("Discrimination because one's behavior does not 'conform to stereotypical ideas' of one's gender can amount to actionable discrimination 'based on sex'" (citing *Howell v. N. Cent. Coll.*, 320 F.Supp. 2d 717 (N.D. Ill. 2004)); *Snelling v. Fall Mountain Reg'l Sch. Dist.*, No. Civ. 99-488-JD, 2001 WL 276975, at *4 (D. N.H. Mar. 21, 2001) ("The plaintiffs respond that the harassment they experienced arose from the perpetrators' sex-based stereotypes of masculinity [T]he plaintiffs articulate an actionable basis for their Title IX claim").

¹²² See generally Goss Graves Statement, *supra* note 37, at 4-7, 9-10.

¹²⁷ 42 U.S.C. § 2000d (2006) ("No person in the United States shall, on the ground of race, color, or national origin, be eXcluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance."); see also *id.* § 2000d-4a(2)(B) (2006), 3(A)(ii) ("For the purposes of this subchapter, the term 'program or activity' and the term 'program' mean all of the operations of ... a local educational agency ..., system of vocational education, or other school system [or] an entire corporation, partnership, or other private organization ... which is principally engaged in the business of providing education"). For a discussion of federal enforcement efforts under Title VI involving students who are targeted in part due to their religion, see Section 6.

¹²⁸ *Id.* § 2000d-1 (2006).

¹²⁹ See *Barnes v. Gorman*, 536 U.S. 181, 185-89 (2002); *Guardians Ass'n v. Civil Serv. Comm'n of N.Y.*, 463 U.S. 582, 597-603 (1983).

- ¹³⁰ See, e.g., *DT v. Somers Cent. Sch. Dist.*, 348 Fed. App'x 697, 699 & n.2 (2d Cir. 2009) ("Because Title VI and Title IX use parallel language, we construe them similarly."); *Whitfield v. Notre Dame Middle Sch.*, No. 09 2649, slip op., 2011 WL 94735 at *3 & n.2 (3d Cir. Jan. 12, 2011) ("We construe Titles VI and IX similarly because they use parallel language."); *Bryant v. Indep. Sch. Dist. No. 1-38 of Garvin County, Okla.*, 334 F.3d 928, 934 (10th Cir. 2003) ("The Court's reasoning in *Davis* guides our resolution of the instant case because Congress based Title IX on Title VI; therefore, the Court's analysis of what constitutes intentional sexual discrimination under Title IX directly informs our analysis of what constitutes intentional racial discrimination under Title VI (and vice versa)."); see also *Barnes v. Gorman*, 536 U.S. 181, 185 (2002).
- ¹³¹ See *Davis*, 526 U.S. at 650; see also, e.g., *Qualls v. Cunningham*, 183 Fed. App'x 564, 567 (7th Cir. 2006) ("To establish a hostile educational environment under Title VI, [the plaintiff] must show that the alleged harassment was severe or pervasive enough to deprive him of access to educational benefits."); *Whitfield*, 2011 WL 94735 at *3 ("The harassment must be 'severe, pervasive, and objectively offensive,' and rise above the level of 'simple acts of teasing and name-calling among school children ... even where these comments target differences in [race].'" (quoting *Davis*, 236 U.S. at 652)).
- ¹³² See *Davis*, 526 U.S. at 650; *Gebser v. Lago Vista Indep. Sch. Dist.*, 524 U.S. 274, 290 (1998); see also, e.g., *Gant v. Wallingford Bd. of Educ.*, 195 F.3d 134, 141 & n.6 (2d Cir. 1999) (citing *Gebser*, 118 S. Ct. at 1996 99).
- ¹³³ See *Davis*, 526 U.S. at 650; *Gebser*, 524 U.S. at 290; see also, e.g., *Bryant*, 334 F.3d at 934 (directing the district court to apply the *Davis* test for deliberate indifference); *Monteiro v. Tempe Union High Sch. Dist.*, 158 F.3d 1022, 1034 (9th Cir. 1998) ("When a district is 'deliberately indifferent' to its students' right to a learning environment free of racial hostility and discrimination, it is liable for damages under Title VI.") (citing *Gebser*, 524 U.S. 274).
- ¹³⁴ See 29 U.S.C. § 794(a) (2006) ("No otherwise qualified individual with a disability in the United States ... shall, solely by reason of her or his disability, be excluded from the participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance"); see *id.* § 794(b)(2)(B)-(3)(A) (2006) ("For the purposes of this section, the term 'program or activity' means all of the operations of ... a local educational agency, system of vocational education, or other school system [or] an entire corporation, partnership, or other private organization ... which is principally engaged in the business of providing education ...").
- ¹³⁵ In addition, Title III of the Americans with Disabilities Act also prohibits *private* educational institutions from discriminating against individuals due to disability. See, e.g., 42 U.S.C. § 12182 (2006) ("No individual shall be discriminated against on the basis of disability in the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any person who owns, leases (or leases to), or operates a place of public accommodation."); *id.* § 12181(7)(J) (2006) ("The following private entities are considered public accommodations for purposes of this subchapter, if the operations of such entities affect commerce ... a nursery, elementary, secondary, undergraduate, or postgraduate private school, or other place of education."). Title III is outside the scope of this report, which addresses prohibitions against harassment in *public* K-12 schools.
- ¹³⁶ See 42 U.S.C. § 12132 (2006) ("[N]o qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by any such entity."); *id.* § 12131(1)(B) ("The term 'public entity' means ... any department, agency, special purpose district, or other instrumentality of a State or States or local government").
- ¹³⁷ See *id.* § 12133 (2006) ("The remedies, procedures, and rights set forth in [29 U.S.C. § 794a] shall be the remedies, procedures, and rights this subsection provides to any person alleging discrimination on the basis of disability"); 29 U.S.C. § 794a(a)(2) (2006) ("The remedies, procedures, and rights set forth in title VI of the Civil Rights Act of 1964 ... shall be available to any person aggrieved by any act or failure to act by an recipient of Federal assistance ... under section 794 of this title.").
- ¹³⁸ See generally *Barnes v. Gorman*, 536 U.S. 181, 185-90 (2002).
- ¹³⁹ See, e.g., *Werth v. Bd. of Dirs. of the Pub. Schs. of Milwaukee*, 472 F. Supp. 2d 1113, 1126 (E.D. Wis. 2007) ("Because the reach of both statutes is the same, claims under these provisions are analyzed together.") (citing *K. M. ex rel. D. G. v. Hyde Park Cent. Sch. Dist.*, 381 F.Supp. 2d 343 (S.D.N.Y. 2005)).
- ¹⁴⁰ See, e.g., *K.M.*, 381 F. Supp. 2d at 359-61. Although a few cases have instead applied legal precedent related to hostile work environment under Title VII, this line began with a case published pre-*Davis*, and does not appear to be the prevailing approach. See, e.g., *Guckenberger v. Boston Univ.*, 957 F. Supp. 306, 313-15 (D. Mass. 1997); *Cabrea-Diaz v. Penn Kidder Campus Jim Thorpe Sch. Dist.*, No. 3:08-2192, slip op., 2010 WL 5818289,

at *11 (M.D. Pa. Aug. 9, 2010) (citing *Guckenberger*); *Derrick F. v. Red Lion Area Sch. Dist.*, 586 F. Supp. 2d 282, 308-09 (M.D. Pa. 2008) (citing *Guckenberger*).

¹⁴¹ See *Davis v. Monroe County Bd. of Educ.*, 526 U.S. 629, 650 (1999); see also, e.g., *Werth*, 472 F. Supp. 2d at 1129; *P.R. ex. rel. Rawl v. Metro. Sch. Dist. of Wash. Twp.*, Slip Copy, No. 1:08-cv-1562-WTL-DML, 2010 WL 4457417, at *5, 7 (S.D. Ind. Nov. 1, 2010).

¹⁴² See *Davis*, 526 U.S. at 650; *Gebser v. Lago Vista Indep. Sch. Dist.*, 524 U.S. 274, 290 (1998); see also, e.g., *Werth*, 472 F. Supp. 2d at 1129; *P.R.*, 2010 WL 4457417, at *7-8.

¹⁴³ See *Davis*, 526 U.S. at 650; *Gebser*, 524 U.S. at 290; see also, e.g., *S.S. v. Eastern Ky. Univ.*, 532 F.3d 445, 453-56 (6th Cir. 2008); *Biggs v. Bd. of Educ. of Cecil County, Md.*, 229 F. Supp. 2d 437, 445 (D. Md. 2002).

¹⁴⁴ The Commission submitted interrogatories and document requests to ED on March 18, 2011. In response to these requests, ED provided data on complaints received through March 21, 2011.

¹⁴⁵ See U.S. Department of Education Response to the U.S. Commission on Civil Rights' Interrogatories and Document Requests at 16 (April 18, 2011) [hereinafter ED Response]. OCR defines "harassment" to "include peer-to-peer harassment, peer-to-peer bullying, and peer-to-peer violence, as well as incidents of harassment, bullying, and violence by school or school-district staff or by related third parties." *Id.* OCR has received 38,974 total complaints during that period. See *id.* at 8.

²⁴⁴ *Id.* at 5-6; see also Conference Call Transcript, *supra* note 228, at 17 (Statement of Russlynn Ali) (“[A]lthough the department does not hold jurisdiction over religion, much of the anti-religious, if you will, bullying that we’re seeing across the country is not because students are Jewish or because students are Muslim or any details about their faith or their worship. It is about the harasser perceiving them as being members of a special ethnic group or a national origin. It is there where we will vigorously enforce the civil rights laws to protect those students from a harassing environment.”). For further discussion of the Dear Colleague Letter’s analysis of Title VI implications for harassment of religious groups, please see *infra* Section 6.

²⁴⁵ Harassment/Bullying DCL, *supra* note 40, at 7-8. For further discussion of the Dear Colleague Letter’s analysis of Title IX implications for harassment of actual or perceived LGBT students and students that do not conform to gender stereotypes, please see *infra* Section 6.

²⁴⁶ Press Release, U.S. Dep’t of Educ., Guidance Targeting Harassment Outlines Local and Federal Responsibility, Oct. 26, 2010, available at <http://www.ed.gov/news/press-releases/guidance-targetingharassment-outlines-local-and-federal-responsibility> (last visited May 3, 2011).

²⁴⁷ Harassment/Bullying DCL, *supra* note 40, at 9.

²⁴⁸ As discussed *supra* Section 5, ED and DOJ reason that Title IX protects all students—including LGBT students—from sex discrimination, and that Title VI protects all students—including those belonging to groups with a common faith—from discrimination based on ethnicity, national origin, or race. DOJ also addresses religion-based discrimination in schools under Title IV of the Civil Rights Act of 1964, 42 U.S.C. § 2000c. ED does not enforce this provision.

²⁴⁹ See, e.g., Statement of Roger Clegg, President & Gen. Counsel, Ctr. for Equal Opportunity, at 7, May 13, 2011, available at <http://www.eusccr.com/6.%20Roger%20Clegg,%20Center%20for%20Equal%20Opportunity.pdf> (last visited June 22, 2011) [hereinafter Clegg Statement] (“After all, ‘sex’ does not mean ‘sexual orientation,’ and it certainly did not mean that in 1972. That’s all there is to it. ... [T]hey have concocted a legal argument that says the use of ‘sexual stereotypes’ is banned by the laws that ban discrimination on the basis of sex, and they are using this argument to bootstrap in a ban on sexual orientation.”); Public Comment of Hans Bader, Senior Att’y & Counsel for Special Projects, Competitive Enter. Inst., at 2, Mar. 22, 2011, available at http://www.mindingthecampus.com/originals/2011/03/by_hans_bader_theres.html (last visited Sept. 9, 2011) (“The [Dear Colleague Letter] incorrectly equates homophobic harassment with sexual harassment forbidden by the sex discrimination law Title IX.”); Marcus Statement, *supra* note 103, at 24-25 app. A (discussing OCR’s prior reluctance to address anti-Semitic harassment under Title VI).

²⁵⁰ See, e.g., ED Response, *supra* note 145, at 24 (“Title IX does not prohibit discrimination based solely on sexual orientation; so OCR does not have jurisdiction over complaints alleging discrimination, including harassment, based on sexual orientation.”).

²⁵¹ Revised Sexual Harassment Guidance, *supra* note 220.

²⁵² *Id.* at 3.

²⁵³ *Id.*

²⁵⁴ See Sexual Harassment DCL, *supra* note 220 (“Longstanding legal authority establishes that harassment of students can be a form of sex discrimination covered by Title IX I am enclosing the Revised Sexual Harassment Guidance: Harassment of Students By School Employees, Other Students, or Third Parties issued by OCR in January 2001.”). Assistant Secretary Monroe’s letter addressed sexual harassment issues generally; it did not specifically discuss sexual harassment of LGBT students or gender-based harassment.

²⁵⁵ Sexual Harassment: It’S Not Academic, *supra* note 35, at 8.

²⁵⁶ *Id.*

²⁵⁷ For further discussion of the Harassment/Bullying Dear Colleague Letter, please see *supra* Section 5.

²⁵⁸ Harassment/Bullying DCL, *supra* note 40, at 7-8; see also Marcus Statement, *supra* note 103, at 23-24 app. A (“The new OCR policy recognizes this legal development [that courts have interpreted sex discrimination to include various forms of sex-stereotyping], which is hardly new, and describes it in terms that are hardly radical”).

²⁵⁹ Harassment/Bullying DCL, *supra* note 40, at 8; see also Marcus Statement, *supra* note 103, at 23 app. A (“[This language] means only that a lesbian student who faces sexist treatment will get the same protections as any other girl. This proposition is entirely uncontroversial.”); Goss Graves Statement, *supra* note 37, at 11 (“[N]o federal law prohibits *per se* LGBT-based bullying or harassment. Although Title IX covers LGBT-related bullying and

harassment when such conduct targets a student's failure to conform to sex stereotypes, it does not prohibit LGBT bullying and harassment more generally.").

- ²⁶⁰ See Brief of the United States as Amicus Curiae, *Pratt v. Indian River Cent. Sch. Dist.*, No. 09-0411 (N.D.N.Y. - ²⁸¹ See, e.g., Ali Statement, *supra* note 6, at 4 ("Title IX does not prohibit discrimination based solely on sexual orientation.").
- ²⁸² See Byard Statement, *supra* note 73, at 7 n.18 ("To be sure, LGBT students may be protected by such laws when they are victims of otherwise covered action—such as in cases where sexual harassment occurs, and the victim of the harassment is a gay student. That protection, however, is not the same as protection against anti-gay harassment affecting that student."); Public Comment of Sen. Al Franken, U.S. Senate, at 3, Apr. 29, 2011,

available at <http://www.eusccr.com/29.%20U.S.%20Sen.%20Al%20Franken.pdf> (last visited June 22, 2011) [hereinafter Franken Comment] ("[S]ince Title IX can only protect LGBT students from bullying based on gender stereotyping, they lack its protection against bullying based on sexual orientation Without Title IX protections, many victims of LGBT bullying, harassment, and discrimination therefore remain without recourse. This is a significant gap in protection for a group of students that currently faces severe harassment and discrimination in schools.").

²⁸³ See, e.g., *Riccio v. New Haven Bd. of Educ.*, 467 F. Supp. 2d 219, 225 (D. Conn. 2006) ("[Defendant] contends that the thrust of the slurs were of a sexual orientation nature and not gender specific. Therefore, [Defendant] argues that Andree does not have a claim for sexual harassment because Title IX does not provide a remedy for discrimination based on sexual orientation.") (citation omitted). It should be noted that the *Riccio* court rejected this argument based on the facts of the case.

²⁸⁴ See, e.g., Public Comment of Rep. Jared Polis & Rep. Ileana Ros-Lehtinen, U.S. House of Representatives, at 2, May 4, 2011, available at <http://www.eusccr.com/30.%20U.S.%20Rep.%20Jared%20Polis%20&%20U.S.%20Rep.%20Ileana%20RosLehtinen.pdf> (last visited June 22, 2011) ("While Title IX of the Education Amendments does afford protections against sex and gender-based discrimination, including harassment, the Congress must empower OCR to do more to properly protect LGBT students by passing explicit statutory protections on the basis of sexual orientation and gender. Such a step would serve to fill a glaring existing gap in our federal civil rights laws that leave one of the most vulnerable students [sic] populations without the protections they need.").

²⁸⁵ Franken Comment, *supra* note 282, at 3. the bill provides, in part: sec. 4. prohibition against discrimination.

(1) IN GENERAL.—No student shall, on the basis of actual or perceived sexual orientation or gender identity of such individual or of a person with whom the student associates or has associated, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance.

(b) HARASSMENT.—For purposes of this Act, discrimination includes harassment of a student on the basis of actual or perceived sexual orientation or gender identity of such student or of a person with whom the student associates or has associated.

S. 555, 112th Cong. (2011). The companion bill in the House of Representatives is H.R. 998, 112th Cong. (2011).

²⁸⁶ H.R. 1648, 112th Cong. (2011); S. 506, 112th Cong. (2011). The Safe Schools Improvement Act would establish state reporting requirements, needs assessment, and technical assistance, and require local educational agency discipline policies, indicators, and grievance procedures, and data collection by the Commissioner for Education Statistics. According to its sponsor, Representative Linda Sanchez, H.R. 1648 was designed "to ensure that schools and districts develop and use comprehensive and effective student conduct policies that include clear prohibitions regarding bullying and harassment ... and ... ensure that States and districts maintain and report data regarding incidents of bullying and harassment" Public Comment of Rep. Linda Sanchez, U.S. House of Representatives, at 1, May 12, 2011, available at <http://www.eusccr.com/31.%20U.S.%20Rep.%20Linda%20T.%20Sanchez.pdf> (last visited June 22, 2011).

²⁸⁷ The DOJ also addresses religion-based discrimination under Title IV.

²⁸⁸ See, e.g., ED Response, *supra* note 145, at 23 ("Although OCR does not have the statutory authority to respond to complaints based solely on religion, a group's common faith does not divest OCR of its Title VI jurisdiction over discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics."); M arcus Statement, *supra* note 103, at 6 ("[Because federal civil rights laws are silent as to religion,] the federal administrative civil rights apparatus lacks jurisdiction to investigate religious discrimination claims in the public schools for cases involving student-on-student harassment or other forms of religious discrimination. By contrast, [OCR], which I once led, would have jurisdiction in those same situations if the basis of the harassment claims were racial, ethnic or disability-related rather than religious.").

²⁹⁰ *Id.*

²⁹¹ *Id.*

²⁹² *Id.*

²⁹³ Religion DCL, *supra* note 224.

²⁹⁴ *Id.*

²⁹⁵ Mr. Marcus has indicated that this policy was not enforced prior to 2004 or between 2004 and 2010. See Marcus Statement, *supra* note 103, at 6 ("[U]ntil 2004, OCR typically refused to investigate anti-Semitism complaints on the grounds that Jews are a religious group, not a racial or national origin group."); see also *id.* at 7 ("Over

the following six years, my OCR successors generally did not adhere to these policy statements [addressed in the 2004 Dear Colleague Letter].”); *id.* at 25 app. A (“OCR’s leadership during the second George W. Bush administration and at the outset of the Obama administration were differently inclined, and they tended to disregard the 2004 policy.”). Current OCR leadership takes a different view, stating that “OCR’s interpretation of its Title VI jurisdiction has not changed” from 2001 to present: “Although OCR does not have the statutory authority to respond to complaints based solely on religion, a group’s common faith does not divest OCR of its title VI jurisdiction over discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics.” ED Response, *supra* note 145, at 23.

²⁹⁶ Religion DCL, *supra* note 224. The 2004 Dear Colleague Letter also addressed the enforcement of Title IX with respect to students who are members of religious groups. Upon describing “allegations of race and sex discrimination against white, male Christian students,” the Letter stated: “While OCR lacks jurisdiction to prohibit discrimination against students based on religion per se, OCR will aggressively prosecute harassment of religious students who are targeted on the basis of race or gender, as well as racial or gender harassment of students who are targeted on the basis of religion.” *Id.*

²⁹⁷ See Letter from Thomas E. Perez, Asst. Att’y Gen., Civil Rights Div., U.S. Dep’t of Justice, to Russlynn H. Ali, Asst. Sec’y for Civil Rights, Office for Civil Rights, U.S. Dep’t of Educ., Sept. 8, 2010, at 1, available at http://www.justice.gov/crt/about/cor/TitleVI/090810_AAG_Perez_Letter_to_Ed_OCR_Title%20VI_and_Religiously_Identifiable_Groups.pdf (last visited June 22, 2010).

³¹⁹ *Id.* at 2. *See also* Marcus Statement, *supra* note 103, at 20-21 app. A ("In fairness, it should be acknowledged that this deviation is not unique to the Obama administration's approach, since the new policy merely reiterates a standard that OCR announced as early as 1994 and which OCR reiterated during the second George W. Bush administration.") (citations omitted).

³²⁰ Eastman Statement, *supra* note 308, at 4 ("[T]he Department's claim that the liability standards of *Davis* do not limit the terms of its funding contracts with school districts is highly misleading—at best.").

³²¹ *Id.*; *see also* Briefing Transcript, *supra* note 7, at 96:20-23 (Eastman Testimony) ("The Department seems to claim such authority when it cites the *Gebser* case from 1998, but I think it's misreading that case.").

³²² *See* Eastman Statement, *supra* note 308, at 4; *see also* Briefing Transcript, *supra* note 7, at 96:9-19 (Eastman Testimony) ("[Congress] may not use its spending power as a pretext to accomplish indirectly what it cannot do directly. ... [I]t is even more clearly the case that an administrative agency cannot impose new conditions on the receipt of federal funding that are not authorized by law."); *id.* at 109:14-20 (Eastman Testimony) ("And the Court has also been very clear that we can't use the spending power to accomplish things that we don't have other authority to accomplish. What OCR seems to be doing here is using its conditions on spending in an effort to obtain a regulatory regime that they could not do directly").

³²³ *See* Eastman Statement, *supra* note 308, at 5-7.

³²⁴ Letter from Arthur R. Goldman, Customer Serv. & Tech. Team Leader, Office for Civil Rights, U.S. Dep't of Educ., to Kimberly A. Tolhurst, Acting Gen. Counsel, U.S. Comm'n on Civil Rights, at 5, July 15, 2011 ("The concern over imposing *retrospective* liability for damages where a school did not have actual knowledge that its actions were unlawful is of no moment in administrative-enforcement proceedings, where the remedies are prospective and where even any prospective loss of federal funding can be absolutely avoided by curing the violation.") (emphasis in original).

- ³²⁵ See, e.g., Ali Letter to Negrón, *supra* note 315, at 4 ("[T]he process of OCR's administrative enforcement requires OCR to make schools aware of civil rights violations and to seek voluntary corrective action to achieve compliance before pursuing fund termination or other enforcement mechanisms.").
- ³²⁶ See, e.g., Marcus Statement, *supra* note 103, at 21 app. A.
- ³²⁷ See Briefing Transcript, *supra* note 7, at 48:24-49:4 ("[W]e do not have jurisdiction and would not take action against single incidents of playground taunting absent something like physical conduct that made a single incident sufficiently severe or pervasive to create a hostile environment.").
- ³²⁸ The standard has also been criticized for allegedly omitting "an objective component—a 'reasonable person' standard—in the assessment of harassment claims." See Public Comment of Foundation for Individual Rights in Education (FIRE), at 3, May 26, 2011, available at <http://thefire.org/public/pdfs/6aefda8e736cc0f8d633980f9549eeae.pdf?direct> (last visited Sept. 9, 2011) [hereinafter FIRE Comment]. It has been alleged that "[t]he loss of the crucial 'reasonable person' standard means that a school's most sensitive students effectively determine what speech is prohibited." *Id.* ED, however, maintains that this analysis is incorrect; it is ED's policy to "consider[] the conduct from both a subjective and objective perspective." See revised sexual harassment guidance, *supra* note 220, at 5 (citations omitted); First Amendment DCL, *supra* note 225 ("OCR's standards require that the conduct be evaluated from the perspective of a reasonable person in the alleged victim's position").
- ³²⁹ See Briefing Transcript, *supra* note 7, at 251:3-254:5 (Negrón Testimony). For further discussion of federalism concerns, please see pp. 68-73.
- ³³⁰ See *id.* at 297:14-298:21 (Volokh Testimony); Public Comment of National Coalition Against Censorship, at 2-7, May 27, 2011, available at <http://www.scribd.com/doc/56492194/Comments-on-Federal-Anti-BullyingPolicy-on-Free-Expression> (last visited Sept. 9, 2011) [hereinafter National Coalition Against Censorship Comment]; FIRE Comment, *supra* note 328, at 2 ("Because of the careful balance struck by the Court in enunciating the *Davis* standard, we believe that any new guidance or legislation must ... explicitly reference or incorporate the *Davis* standard to ensure that students' right to free expression is not inadvertently compromised by schools' efforts to address and eliminate harassment."). For further discussion of First Amendment concerns, please see pp. 74-84.
- ³³¹ See, e.g., Marcus Statement, *supra* note 103, at 22 app. A ("OCR would face a steep challenge in defending its policy in federal court, given that the Supreme Court rejected the single-incident approach based not upon such issues as punitive damages or lawyers' fees but upon its assessment of congressional intent in drafting the relevant language.").
- ³³² FIRE Comment, *supra* note 328, at 3.
- ³³³ See revised sexual harassment guidance, *supra* note 220, at 5.
- ³³⁴ See Ali Letter to Negrón, *supra* note 315, at 5. In fact, OCR, has used somewhat different terminology throughout its guidance documents on harassment. For instance, its 1994 Racial Harassment guidance used the term "interfere with or limit," see Racial Incidents and Harassment Against Students Guidance, *supra* note 222, at 11,449 ("A violation of title VI may also be found if a recipient has created or is responsible for a racially hostile environment—i.e., harassing conduct (e.g., physical, verbal, graphic, or written) that is sufficiently severe, pervasive or persistent so as to interfere with or limit the ability of an individual to participate in or benefit from the services, activities or privileges provided by a recipient.") (emphasis added), and its 2000 Disability Dear Colleague Letter used the term "adversely affect." See Disability DCL, *supra* note 63 ("A hostile environment may exist even if there are no tangible effects on the student where the harassment is serious enough to adversely affect the student's ability to participate in or benefit from the educational program.") (emphasis added).
- ³³⁵ Office for civil rights, u.s. dep't of educ., sexual harassment guidance (1997) available at <http://www2.ed.gov/about/offices/list/ocr/docs/sexhar01.html> (last visited June 8, 2011) ("sufficiently severe, persistent, or pervasive to limit a student's ability to participate in or benefit from an education program or to create a hostile or abusive educational environment") (emphasis added).
- ³³⁶ Notice, Revised Sexual Harassment Guidance: Harassment of Students by School Employees, Other Students, or Third Parties, 65 Fed. Reg. 66,092, 66,096-97, Nov. 2, 2000 (citations omitted).
- ³³⁷ See Racial Incidents and Harassment Guidance, *supra* note 222, at 11,449 ("A violation of title VI may also be found if a recipient has created or is responsible for a racially hostile environment—i.e., harassing conduct (e.g., physical, verbal, graphic, or written) that is sufficiently severe, pervasive or persistent so as to interfere with or limit the ability of an individual to participate in or benefit from the services, activities or privileges provided by a recipient.") (emphasis added).

- ³³⁸ Negrón Statement, *supra* note 308, at 5; *see also* Briefing Transcript, *supra* note 7, at 251:20-23 (Negrón Testimony) ("OCR's position confuses the standards between liability and enforcement, making it more difficult for school officials to understand the requirements of the law.").
- ³³⁹ Briefing Transcript, *supra* note 7, at 252:17-253:17 (Negrón Testimony) ("Courts are starting to use the OCR standard, granting the Department administrative deference for guidance that has not the same weight as officially promulgated rules under the Administrative Procedures Act. ... Our fear is that plaintiffs' lawyers may be emboldened by such an approach to pursue litigation against schools.").
- ³⁴⁰ Negrón Statement, *supra* note 308, at 3.
- ³⁴¹ *Id.* at 3-4; *see also id.* at 4 ("This standard may needlessly drain school resources and attention from the more crucial task of fostering an appropriate climate while minimizing the professional discretion of local educators to craft workable, individualized solutions.").
- ³⁴² Ali Statement, *supra* note 6, at 6.
- ³⁴³ Ali Letter to Negrón, *supra* note 315, at 6.
- ³⁴⁴ *Id.* Similarly, DOJ stated, "we absolutely think that schools are in the best position to address harassment and ensure the safety of their school environments and that's why, first of all, we only get involved when there has been a failure of the school district to take the necessary steps." Briefing Transcript, *supra* note 7, at 49:22-50:3 (Samuels Testimony).
- ³⁴⁵ Ali Statement, *supra* note 6, at 6.
- ³⁴⁶ *Id.* at 7.
- ³⁴⁷ Negrón Statement, *supra* note 308, at 5.
- ³⁴⁸ *Id.* at 6.
- ³⁴⁹ *Id.* at 5.
- ³⁵⁰ *Id.* at 6. *See also id.* at 9 ("[F]ederalizing' bullying may chill the ability of educators to respond in otherwise appropriate ways for fear of agency action or litigation. ... [I]f every instance implicates a federal right, educators will have no choice but to take formal steps in even the most mundane of cases to avoid agency liability and prepare for a legal defense. Such an insalubrious approach places form over function, restricting the educator's ability to use discretion and to respond effectively with the fewest resources necessary to resolve a conflict."); Public Comment of Neal McCluskey, Assoc. Dir., Ctr. for Educ. Freedom, Cato Inst., at 5, *available at* <http://www.eusccr.com/28.%20Neal%20McCluskey,%20Cato%20Institute.pdf> (last visited June 22, 2011) [hereinafter McCluskey Comment] ("The major problem stemming from such after-the-fact governance is clear: The strong incentive it gives school officials is to overreact to incidents that could even remotely be connected to group-based harassment or bullying, even if they are not."); Statement of Kenneth S. Trump, President and CEO, Nat'l Sch. Safety and Sec. Serv., Inc., at 9-10, May 13, 2011, *available at* <http://www.eusccr.com/26.%20Kenneth%20Trump,%20National%20School%20Safety%20and%20Security%20Services,%20Inc.pdf> (last visited June 22, 2011) [hereinafter Trump Statement] (describing the Dear Colleague Letter as "counterproductive" and "overreach," and predicting increased litigiousness); *id.* at 9 ("[school administrators'] concerns were not one of being questioned or second-guessed, but a concern about the role, experience, competence, and legitimacy of federal civil rights investigators with school climate and discipline issues (bullying).").
- ³⁵¹ Briefing Transcript, *supra* note 7, at 278:9-13 (Negrón Testimony); *see also id.* at 65:20-22 (Clegg Testimony) ("[L]ocal schools are going to be caught in this bind where they're afraid of being sued if they do, they're afraid of being sued if they don't.").
- ³⁵² Negrón Statement, *supra* note 308, at 7; *see also id.* ("School boards across the country are doing this right now, and have been for the past several years. State legislatures and educational agencies are passing laws and model policies to direct school boards' policy formation. ... At last count, 45 states had passed an anti-bullying statute. The vast majority of these statutes require local school boards to address bullying through policy, with the participation of the community.").
- ³⁵³ *Id.* at 9; *see also* Briefing Transcript, *supra* note 7, at 143:3-12 (Clegg Testimony) ("[T]he federal government's involvement will actually make matters worse, because it's much more difficult for the federal government to draw these nuanced lines on the basis of local conditions, what was actually happening in the school, what the student actually said, all of that—much more difficult for the federal government to design a policy that is going to be sensitive to all that—than leaving it to the local schools.").
- ³⁵⁴ Briefing Transcript, *supra* note 7, at 286:13-17 (Negrón Testimony).
- ³⁵⁵ *Id.* at 286:18-22.
- ³⁵⁶ *See, e.g.,* McCluskey Comment, *supra* note 350, at 5 ("[W]hat is the 'right' way to handle bullying— especially in light of free speech and equal protection concerns—is far from a settled matter, which is all the more reason that

the federal government should be very reticent about acting even if it has the authority to do so."); Clegg Statement, *supra* note 249, at 5 ("I would rather have the lines drawn at the most local level possible. ... The presumption should be for only a limited federal role in matters of local schools and local school discipline. Sometimes—as with racial discrimination—that presumption can rightly be overcome. But I cannot imagine that this is the case here."); Briefing Transcript, *supra* note 7, at 63:25-64:5 (Clegg Testimony) ("[T]his is a very difficult area with a lot of difficult line-drawing that has to be done. When does protected speech become unprotected speech, and become harassment? When does harassment become a threat? When does a threat become an actual physical assault? And so forth."); *cf.* Trump Statement, *supra* note 350, at 7 ("Other questions include not only how will school climate be defined, but who will be defining it? Will it be D.C. bureaucrats? Will the definition be influenced by special interest groups lobbying for their agendas under 'anti-bullying' and 'school safety' labels?").

³⁵⁷ Clegg Statement, *supra* note 249, at 4.

³⁵⁸ Briefing Transcript, *supra* note 7, at 113:4-7 (Clegg Testimony).

³⁵⁹ See McCluskey Comment, *supra* note 350, at 5 ("In keeping with the genius of the American federal design, it is better to let fifty states experiment with different remedies than to impose one on all Americans. That allows numerous potential remedies to be tried, and prevents a poor—or even dangerous—one from being imposed on the entire nation.").

³⁶⁰ See Negrón Statement, *supra* note 308, at 7 ("A bullying incident is best addressed by local entities taking into account the characteristics and priorities of the community.").

³⁶¹ Briefing Transcript, *supra* note 7, at 154:4-11 (Byard Testimony); *see also id.* at 283:20-22 (Aaberg Testimony) ("[W]ith all the kids around the country coming to me and telling me what's going on in their district, obviously local involvement is not working.").

³⁶² *See id.* at 88:5-17 (Byard Testimony):

A core challenge we face is the fact that bias-based bullying complicates adult response. Whether out of fear of controversy, failure to recognize the seriousness of the behavior, or active indifference to the fate of the students involved, adults charged with the education and care of our children are not consistently living up to their responsibilities. Federal leadership is necessary to make the basic level of the extent of their responsibilities crystal clear, and to assure those who fear controversy or backlash that they are doing the right thing.

See also, e.g., Singh Statement, *supra* note 104, at 3 ("[W]e believe that vigorous federal intervention is needed to hold schools and school districts accountable for their actions and, just as importantly, their inaction.").

¹⁶ USCCR Report, *supra* note 2, at 22.

¹⁷ "School-based harassment, bullying, and peer victimization are the most common topics in the literature on LGB youth. This emphasis may be due to the role of schools in child and adolescent socialization and development and the increasing focus over the past 20 years on schools as a primary site of conflict, victimization, and activism for young people who are known or perceived to be LGBT."

The Institute of Medicine of the National Academies, "The Health of Lesbian, Gay, Bisexual, and Transgender People: Building a Foundation for Better Understanding," Washington, D.C., 2011, p. 158, available at <http://www.iom.edu/Reports/2011/The-Health-of-Lesbian-Gay-Bisexual-and-Transgender-People.aspx>.

(Hereinafter "IOM Report.") The IOM Report further states that: [s]chool victimization based on known or perceived sexual orientation and gender identity has been documented consistently in studies of LGB and, more recently, transgender adolescents. A community-based study of LGB youth aged 21 or younger (n = 350) (D'Augelli et al., 2002) found that school-based victimization was widespread for LGB youth and that an association existed between this victimization and mental health and posttraumatic stress symptoms. The study results showed that earlier recognition of same-sex feelings, self-identification as LGB, and disclosure of sexual orientation were correlated with increased high school victimization. Similarly, youth who were open about their sexual orientation or exhibited gender-atypical behavior were targets for victimization. Likewise, a series of community school climate surveys conducted since 1999 has documented extensive verbal and physical harassment and discrimination among LGBT students in schools (Kosciw et al., 2007, 2008).

²⁸ These professional groups include the American Academy of Pediatrics, American Association of School Administrators, American Counseling Association, American Federation of Teachers, American Psychological Association, American School Counselor Association, American School Health Association, Interfaith Alliance Foundation, National Association of School Psychologists, National Association of Secondary School Principals, National Association of Social Workers, National Education Association, and the School Social Work Association of America. See "Psychiatric Treatment and Sexual Orientation, Position Statement No. 199820," American Psychiatric Association, 1993, available at: <http://www.psych.org/Departments/EDU/Library/APAOfficialDocumentsandRelated/PositionStatements/199820.aspx>. Corollary to the lack of pathology inherent in a homosexual orientation is the reported overall positive mental health of sexual minority youth. As the USCCR Report quotes from the IOM Report, [i]t is important to note that LGBT youth are typically well adjusted and mentally healthy. Research based on probability samples with LGB youth consistently indicates that the majority do not report mental health problems. Regarding transgender youth, although no data from national probability samples are available, studies with sizable convenience samples indicate that many, if not most, of those youth do not report mental health problems.

USCCR Report, *supra* note 2, at footnote 98, in pertinent part: "See IOM Study, *supra* note 83, at 125."

²⁹ IOM Report, *supra* note 17, at 158, citing Birkett et al., 2009.

³⁰ *Id.* With regard to school attendance, Friedman's meta-analysis found that sexual minority youth are "240% more likely to miss school due to fear that they would be unsafe at school or on [the] way to or from school,"³⁰ and that "16% of lesbian females, 23% of bisexual females, 14% of gay males and 23% of bisexual males missed school due to fear." Friedman Comment, *supra* note 19, at 2. Further, gay, lesbian, and bisexual youth are approximately three to four times more likely than their heterosexual peers to have missed at least one day of school within the thirty days prior to the survey "because they felt they would be unsafe at school or on their way to or from school." Olsen, Emily O'Mally, McManus, Tim, Kinchen, Steve, Chyen, David, Harris, William A., Wechsler, Howell, "Sexual Identity, Sex of Sexual Contacts, and Health-Risk Behaviors Among Students in Grades 9-12 – Youth Risk Behavior Surveillance, Selected Sites, United States, 2001 – 2009," *Morbidity and Mortality Weekly Report*, Vol. 60, U.S. Department of Health and Human Services, Centers for Disease Control and Prevention, June 6, 2011, p. 12, available at <http://www.cdc.gov/mmwr/pdf/ss/ss6007.pdf>. (Hereinafter "CDC Report.")

³¹ *Id.* at 49.

Regarding its underlying data source, Youth Risk Behavior Surveillance System (hereinafter "YBRSS") reports from an array of states over nine years, the CDC reports that YBRSS is the only public health surveillance system in the United States that monitors, among interested states and large urban school districts, the prevalence of health-risk behaviors and selected health outcomes among population-based samples of sexual minority youths defined by sexual identity and by the sex of sexual contacts. *Id.* at 43.

³² The CDC also reported that African-American sexual minority youth engaged in approximately half of a large array of measured risky behaviors more often than their same-race, heterosexual peers, and that Latino/a and white sexual minority youth did so roughly two-thirds as often.

³⁴ *Id.* at 21.

³⁵ See, e.g., *id.* at 23 - 28.

³⁶ See, e.g., *id.* at 30 - 32.

³⁷ “Structural stigma” is the collective process by which majority class members give permission to the society as a whole to victimize minority class members. This permission also facilitates perpetration of harassment by members of one minority upon members of other minorities. Structural stigma plays an important role in condoning students’ identity-based targeting of others due to race or ethnicity, religion, sex, disability status, and sexual minority and/or gender non-conforming youth status. This appears to further enhance the negative impacts of harassment upon youth who are members of more than one minority class, such as those who are both racial/ethnic-origin minorities and sexual minority youth, as this Statement discusses. This concept of stigma is the underpinning of the way in which society condones, or at least fails to sufficiently intervene against, the identity-based harassment which plagues each of the demographic classes of students discussed in this project. (See Statements of Dr. Gregory Herek, *supra* note 24, and Dr. Ilan Meyer, available at <http://www.eusccr.com/10.%20Ilan%20Meyer,%20Columbia%20Universirt.pdf>. See also USCCR Report, *supra* note 2, at footnote 90.)

³⁸ IOM Report, *supra* note 17, at 32.

³⁹ Friedman, et al., *supra* note 18, at 1.

⁴⁰ In a similar vein, research indicates that “sexual abuse by parents was more frequently cited as a reason for leaving home among gay and lesbian (21%) [homeless youth] that it was among heterosexual [homeless youth].”

See Corliss, Heather L., Ph.D., Goodenow, Carol S., Ph.D., Nichols, Lauren, B.A., and Austin, S. Bryn, Sc.D., “High Burden of Homelessness Among Sexual-Minority Adolescents: Findings from a Representative Massachusetts High School Sample,” *Journal of Public Health*, Vol. 101, No. 9, Sept. 2011, p. 1683, 1686, published online July 21, 2011 with abstract available at <http://ajph.aphapublications.org/cgi/content/abstract/101/9/1683> and full copy on file with the author. ⁴¹ Analysis of data from two recent state-administered Massachusetts Youth Risk Behavior Surveys which drew from a large, probability-based sample pool determined that: [a]pproximately 25% of lesbian and gay adolescents and 15% of bisexuals reported homelessness as compared with 3% of the exclusively heterosexual adolescents. ... [Further, n]early 20% of the homeless youths in this study identified themselves as lesbian, gay, or bisexual. This study concluded that, overall, “rejection and victimization within the family related to minority sexual orientation likely contribute to a greater risk of homelessness among sexual minority youth.

⁴⁸ *Id.*

⁴⁹ Meta-analysis indicates that:

[s]pecific factors related to sexual-minority status, including homophobic victimization and stress [citation omitted] are associated with suicidal behavior. In a study of 528 self-identified LGB youth aged 15-19, D’Augelli and colleagues (2005) found that recognizing same-sex attraction, initiating same-sex sexual activity, or appearing gender nonconforming at earlier ages was associated with reported suicide attempts in LGB youth; *this association may be exacerbated by experiences of victimization and maltreatment* [emphasis added, citations omitted.]

IOM Report, *supra* note 17, at 148 - 149.

⁵⁰ *Id.* at 149, citing D’Augelli et al. and Ryan et al.

⁵¹ Specifically,

LGBT young adults who reported high levels of LGBT school victimization during adolescence were 5.6 times more likely to report a suicide attempt that required medical care, [and] 2.6 times for likely to report clinical levels of depression ... , compared with peers who reported low levels of school victimization. [citation omitted.] Public Comment of Caitlin Ryan, Ph.D., ACSW, Director, Family Acceptance Project, Marian Wright Edelman Institute, San Francisco State University, at 2, May 23, 2011.

The second relevant study demonstrated that sexual minority “young adults who did not socially conform to gender roles as adolescents reported higher levels of anti-LGBT victimization, with significantly higher levels of depression and decreased life satisfaction in young adulthood.” [citation omitted.]

Id.

⁵² Public Comment of Adrienne Mundy-Shephard, Esq., at 8, May 6, 2011. The following quote best summarizes the issues presented when the questions involve sexual minority and gender non-conforming youth of color. Adrienne Mundy-Shephard, Esq. advises that: when considering the bullying of sexual minority youth of color, we should be mindful of the common theme that emerges from qualitative studies of sexual minority people of color: the perception that their racial and sexual identities are in conflict (Chung & Katayama, 1998; Dube & Savin-Williams, 1999; Hahm & Adkins, 2009; Narváez et al., 2009). In their study of 23 black, Asian and Latino gay and bisexual male youth, Dube and Savin-Williams found that a number of the youth felt pressure to choose between their ethnic and sexual identities, and that their “dual identities may be distinct constructs that do not become integrated” (1999, p. 1396). Similarly, in Chung and Katayama’s study of gay and lesbian Asian-American adolescents, they found that those who strongly endorse their traditional Asian culture and beliefs are likely to face barriers in developing a positive sexual minority identity, while those who strongly identify with U.S. (i.e., white) sexual minority culture may have problems dealing with their Asian identity because of racism encountered by members of the larger (predominantly white) gay community (1998). Building on the theme of identity conflict, Hahm and Adkins (2009) emphasize the importance of developing an integrated identity that allows API sexual minority youth to develop their minority identities in such a way that they are able to exist in both worlds, rather than feeling compelled to choose between either their racial or sexual minority identities. Finally, in Narváez et al.’s study of black and Latino sexual minority young people, a common theme concerned the incompatibility of sexual minority identity with minority status. For example, a Mexican lesbian described herself as feeling like “a traitor to [her] own race” while a black lesbian spoke of having it made clear to her that “being queer was in some sense a betrayal of [her] blackness.” (2009, p. 64). Despite these real or imagined conflicts, the literature suggests that a positive self-image cannot be achieved without effectively dealing with one’s minority identities in tandem (Chung & Katayama, 1998; Dube & Savin-Williams, 1999; Hahm & Adkins, 2009). Sexual minority students of color are more vulnerable to negative academic and mental health outcomes precisely because of the difficulty in reconciling their dual identities, and their victimization on multiple fronts: by both outsiders, i.e., straight whites, and by those who are theoretically part of their in-groups, i.e., non-sexual minority members of their racial groups and white sexual minority people. Given these intersections – and the tensions inherent in these intersections – it is crucial that researchers of sexual minority youth issues acknowledge the existence of sexual minority youth of color, and the ways in which their sexual minority status informs their status as people of color, rather than viewing youth through a single lens, i.e., as either sexual minorities or as racial/ethnic minorities. For example, Klein (2006) writes that “adolescent members of racial or ethnic minority groups can usually turn to others in the group -- particularly family members and peers -- for reassurance and assistance in dealing with societal hostility and developing a positive self-image,” but that “gay and lesbian adolescents do not consider family to be a source of support and understanding” (p. 43). Within this frame, sexual minority youth of color do not exist: either a young person is a (straight) member of a racial/ethnic minority group and has the advantage of family and peer support to deal with issues of racism, or a young person is an sexual minority-identified (white) person who lacks the advantage of such support to deal with homophobia. Such observations ignore the fact that sexual minority youth of color appear to be more reluctant to seek family support than their white peers (Daley et al., 2007). In attempting to demonstrate the lack of family support that sexual minority youth have, researchers may overlook the fact that the sexual minority youth of color are often least likely to benefit from family supports. As Daley et al. write about the experience of sexual minority youth of color, “the overwhelming white representation of lesbian and gay communities juxtaposed with the dominant heterosexual imagery of racialized communities helps to articulate the struggle for queer youth of color. They belong to both communities, yet their memberships in each remain contested” (2007, p. 22). When examining the impacts of bullying and harassment on sexual minority youth, we must therefore be cognizant that the interaction of racial/ethnic and sexual minority identity may increase the likelihood of victimization while reducing the likelihood of support.

⁵⁶ *Id.* at 41.

⁵⁷ *Id.* at 40.

⁵⁸ Of particular note is the increasing use of computerized surveys for collecting self-report data that has accompanied advances in technology and its accessibility. Most pertinently to this project and sexual minority and gender non-conforming youth,

[T]he use of computer-assisted data collection ... [has the] potential for collecting sensitive information in a manner that increases the confidentiality of responses. By not having the interviewer read the questions or be involved in the recording of answers, the respondent does not have to reveal potentially embarrassing behavior directly to another person. In addition, the responses cannot be overheard by other people (e.g., family members or teachers) who might be nearby.

Id. at 62, referencing Tourangeau, Roger, and Smith, Tom W., "Asking Sensitive Questions: The Impact of Data Collection, Mode, Question Format, and Question Content," *Public Opinion Quarterly*, Vol. 60, 1996, p. 275.

Given the culturally-sensitive nature of a sexual minority or gender non-conforming youth identity and of non-heterosexual sexual behavior, it appears reasonable to extend this principle of the potentially enhanced reliability of computer-collected data to sexual minority and gender non-conforming youth.

⁶⁴ *Id.* at 99. Note: The IOM Report defines the term "LGBT" to mean "lesbian, gay, bisexual, and transgender," in concert with the Commission's Report and this Statement. *See* IOM Report, *supra* note 17, at xviii.

⁶⁵ The Institute of Medicine further explains that: [s]cientific and methodological challenges exist in the design and implementation of most sample surveys and research studies. This is particularly true of studies of relatively small populations on topics construed by the respondent to be of a sensitive nature. Health research studies of LGBT populations are often viewed in this way. Methodological challenges, however, can be overcome when careful attention is paid to scientific rigor and respectful involvement individuals who represent the target population. Scientific rigor includes incorporating and monitoring culturally competent study designs, such as the use of appropriate measures to identify participants and implementation processes adapted to unique characteristics of the study population. Respectful involvement of the study population, in this case LGBT people, refers the involvement of individuals and community representatives in the research process, from decisions about the study purpose and methods, to ongoing consultation and data gathering, to dissemination of results (Minkler and Wallerstein, 2002).

Id. at 123 – 128, with data charts interposed.

⁶⁶ By logical extension, this principle should hold true with regard to the other demographic classes at issue here.

- ⁷³ The plaintiff students report, among other manifestations of harassment, being called an array of derogatory names, touched in sexually suggestive manners, tripped, pushed into lockers and a trash can, choked, stabbed, and told to commit suicide. Plaintiff students further report numerous attempts to engage the assistance of school staff in remediating the harassment, only to be ignored or given meaningless suggestions. The lawsuit seeks relief from sex discrimination and gender-based harassment under the Fourteenth Amendment Due Process Clause, the Fourteenth Amendment Equal Protection Clause, and Title IX of the Education Amendments Act of 1972 (20 USC sec. 1681 et seq.). - ⁹⁰ In light of the structural stigma and family support concerns discussed in the USCCR Report and elsewhere in this Statement, there may well be special sensitivities and risks with schools' communication of peer-to-peer problems to the families of sexual minority and gender non-conforming youth.

End Notes for Dissent and Rebuttal Statement of Commissioners Gaziano and Kirsanow, with Which Commissioner Heriot Concur

- ¹ It is the general practice of the Commission, at least in recent years, not to set forth ultimate conclusions in the body of its reports, and to leave such conclusions to the formal "findings" and "recommendations" that are discussed and separately voted on by the eight commissioners. The Commission did not attempt to resolve the lawfulness or prudence of OCR's departure from the legal standards set forth in Supreme Court decisions in any manner.
- ² 103 CONG. RECORD 13,897 (1957) (statement of Sen. Lyndon Johnson).
- ³ ED and DOJ believe they can define the conduct that constitutes prohibited harassment under federal law much more broadly than has the Supreme Court. The differences in the substantive legal standards are discussed in the next section of this statement, but none of the data in the report are relevant to the administration's definition of prohibited federal harassment either. In short, the analysis in this section does not depend on adopting the Supreme Court's definition of federally prohibited harassment rather than the administration's.
- ⁴ The National Center for Education Statistics estimated there were 55.4 million elementary and secondary students in the United States in fall 2010. U.S. DEP'T OF EDUC., DIGEST OF EDUCATION STATISTICS: 2010, Table 1, Projected number of participants in educational institutions, by level and control of institution: Fall 2010, available at http://nces.ed.gov/programs/digest/d10/tables/dt10_001.asp?referrer=report.
- ⁵ See, e.g., Commission Briefing Transcript (May 13, 2011) [hereinafter Briefing Transcript] at 47 (Jocelyn Samuels answering Commissioner Kirsanow that DOJ does not keep data tracking complaints it receives); 103 (panel of Fatima Goss Graves, Roger Clegg, Gregory Herek, Ilan Meyer, and John Eastman had no response to Commissioner Kirsanow's question of whether ED, DOJ, or any other entity had data tracking the number of complaints relating to harassment of protected classes); 307 (Ken Trump answering a question from Commissioner Gaziano: "[T]here is no historical data on bullying, to my knowledge, especially at the federal

level for an extended period of time."), available at <http://www.eusccr.com/PeerBullying%20May%2013%202011%20Transcript.pdf>.

- ⁶ Forty-seven states and the District of Columbia have anti-bullying statutes. Hawaii is the most recent state to pass an anti-bullying statute, which was signed into law on July 11, 2011. Two of the three states that do not have anti-bullying statutes, Michigan and Montana, have statewide regulations. See NAT'L SCHOOL BOARDS ASS'N, STATE ANTI-BULLYING STATUTES JULY 2011, available at <http://www.nsba.org/SchoolLaw/Issues/Safety/Table.pdf>; H.B. 688, 2011 Sess. (Haw.). We do not necessarily endorse all of these laws; we have not closely reviewed them. Commissioner Heriot notes in her accompanying dissent that some state anti-bullying laws and regulations may have unintended consequences. See also Winnie Hu, *Bullying Law Puts New Jersey Schools on Spot*, N.Y. TIMES, Aug. 30, 2011. We cite such state laws here primarily because the proponents of a new federal law bear the burden of demonstrating that it is not duplicative and will not undermine (by preempting and/or conflicting with) existing law. As we indicate later in the rebuttal portion of this statement, we also have independent reasons to believe that increased federal intervention would cause more harm than good in this area.
- ⁷ Not only did the Commission not define bullying or harassment in its report, a majority of the commissioners also refused to do so when debating the findings that would accompany the report. And the majority still purported to make a finding that "bullying and harassment . . . are harmful to American youth." When the Commission was voting on the proposed finding, Commissioner Gaziano objected that "bullying" was a moving target and some scholars were even beginning to define "bullying" downward to include parents not inviting everyone in their kids' class to their birthday parties at their homes. Commission Transcript at 19 (Aug. 12, 2011); see also Hans Bader, *Schools Use "Bullying" as a Pretext to Violate Students' Rights to Free Association and Freedom of Speech*, OPENMARKET.ORG, Aug. 10, 2011 (noting that bullying also is coming to mean wielding "popularity" to exclude others and offensive "eye rolling."). Thus, Gaziano proposed to amend the finding to conform to the Commission's purported review of federal law, limiting it to "serious, pervasive and objectively offensive" conduct constituting harassment under federal law. Commissioners Castro, Thernstrom, Yaki, and Achtenberg rejected the amendment and offered no clarification of their own, preferring to leave it vague. Indeed, Vice Chair Thernstrom admitted the finding "doesn't say anything" and is "like a talking point of a politician" but then provided the decisive vote to prevent it from saying anything and keep it like a politician's talking point. See Commission Transcript at 21-22 (Aug. 12, 2011).
- ⁸ All non-scientific polls should have been deleted, especially those from advocacy groups. For example, the GLSEN 2009 and Harris Interactive 2005 surveys are from different types of self-selecting respondents, the first of which is also influenced by the websites that solicit their views. Such self-selective surveys and suspect data serve no purpose but to mislead. Part of the AAUW study used the Harris Interactive online method, which is not a probability sample. The report at footnote 16 cites a press release from the American Academy of Child & Adolescent Psychiatry, but the press release does not indicate the kind of surveys it is publicizing. The Massachusetts Advocates for Children report did not use a probability sample and had a heavy selection bias. Parent respondents to an online survey were informed that data and examples provided would be used to support the passage of an act addressing bullying of children with autism. Report at 15 n. 69.
- ⁹ Inst. of medicine of the nat'l acads., bd. on the health of select populations, committee on lesbian, gay, bisexual, & transgender health issues & research gaps & opportunities, the health of lesbian, gay, bisexual, and transgender people: building a foundation for better understanding 105 (2011).
- ¹⁰ See Anthony R. D'Augelli et al., *Suicidality Patterns and Sexual Orientation-Related Factors Among Lesbian, Gay, and Bisexual Youths*, 31 Suicide And Life-Threatening Behavior 250, 252 (2001), cited in the report at 20 n.97.
- ¹¹ See Report at 3 & nn.3, 5 (citing National Center for Education Statistics and Bureau of Justice Statistics study; National Education Association study). The report on page 6 cites a study where students reported being "bullied, teased, or taunted" (emphasis added). Another study relates that students reported being subject to "hate-related words." Report at 8. The AAUW study, subtitled "Bullying, Teasing, and Sexual Harassment," defined sexual harassment to mean "unwanted sexual behavior that *interferes with your life*. Sexual harassment is not behaviors that you like or want (for example wanted kissing, touching, or *flirting*)." Report at 10 n.42 (emphasis added). Because federal jurisdiction covers only objectively serious and persistent harassment, based on suspect classifications, that the schools know about (or should know about if ED is correct) and that they are indifferent to, it is misleading to quote even reliable data on various categories of insults and slights that do not trigger federal jurisdiction.
- ¹² See Mark S. Friedman et al., *A Meta-Analysis to Examine Disparities in Childhood Sexual Abuse, Parental Physical Abuse, and Peer Victimization Among Sexual Minority and Sexual Nonminority Individuals*, AMER. J. PUB.

HEALTH, Vol. 101, Issue 3 (2010) ("These data were collected through retrospective self-reports, which may be biased.").

- ¹³ See generally Thea F. van de Mortel, *Faking It: Social Desirability Response Bias in Self-Report Research*, 25 AUSTL. J. ADVANCED NURSING 40 (2008) (discussing tendency of questionnaire and interview respondents to present favorable image of themselves, especially to socially sensitive questions). Self reporting may work reliably well when asking respondents objectively verifiable questions such as how many cars they own or how many bathrooms they have in their homes. But in contrast to such "census-type" questions, self-reporting is much less certain to elicit a truthful response to socially sensitive questions without any likelihood of verification.
- ¹⁴ The Commission majority also rejected an additional finding that we offered to prominently warn readers that much of the data in the report came from advocacy organizations, was not independently verified by the Commission, and used definitions of harassment that vary from the definition of harassment under federal law. Thus, not only are the data in the report unreliable and somewhat contradictory, but a majority of commissioners did not even want to warn readers of the underlying problems that might make them so. See Commission Transcript at 61-63 (Aug. 12, 2011).
- ¹⁵ 526 U.S. 629, 650 (1999) (emphasis added).
- ¹⁶ *Id.* at 645-47.
- ¹⁷ Russlynn Ali, Asst. Sec'y for Civil Rights, U.S. Dep't of Educ., Dear Colleague Letter: Harassment and Bullying at 2 (Oct. 26, 2010) [hereinafter Dear Colleague Letter], available at <http://www2.ed.gov/about/offices/list/ocr/letters/colleague-201010.pdf>.
- ¹⁸ *Davis*, 526 U.S. at 652-53 (unlikely that Congress intended that a single instance could be sufficiently severe to create liability); see also Prepared Testimony of Kenneth L. Marcus Before the U.S. Commission on Civil Rights at 22 (May 13, 2011) ("OCR would face a steep challenge in defending its policy in federal court, given that the Supreme Court rejected the single-incident approach based not upon such issues as punitive damages or lawyers' fees but upon its assessment of congressional intent in drafting the relevant language.").
- ¹⁹ Dear Colleague Letter, *supra* note 17, at 2 ("Harassment does not have to . . . involve repeated incidents."); Report at 4-5 (citing Briefing Transcript, *supra* note 5, at 48 (Samuels Testimony)).
- ²⁰ Francisco Negron of the National School Boards Association testified that some lower courts are starting to use the OCR standard, granting deference to OCR's guidance. Briefing Transcript, *supra* note 5, at 249. Negron cited as an example *T.K. v. New York City Dep't of Educ.*, 2011 WL 1579510 (E.D.N.Y. April 26, 2011), where the court found the October 26, 2010 Dear Colleague Letter to be "useful" in deciding "when a school is required to act, and what type of response is required." *Id.* at *27. As we explain below, we think such deference is erroneous but it has understandable consequences, whether right or wrong.
- ²¹ Public Comment of FIRE at 3 (May 26, 2011).
- ²² Report at 67 n.328 (citing Stephanie Monroe, Asst. Sec'y for Civil Rights, U.S. Dep't of Educ., Dear Colleague Letter: Sexual Harassment Issues (Jan. 25, 2006)).
- ²³ Dear Colleague Letter, *supra* note 17, at 2.
- ²⁴ See, e.g., *Pennsylvania State Police v. Suders*, 542 U.S. 129, 146-47 (2004) ("For an atmosphere of sexual harassment or hostility to be actionable, . . . the offending behavior must be sufficiently severe or pervasive to alter the conditions of the victim's employment and create an abusive working environment.") (internal quotation marks omitted).
- ²⁵ See Public Comment of FIRE, *supra* note 21, at 3 ("This is problematic because 'limit' is a broad term that could encompass effects of widely varying severity, setting a far lower bar for conduct that constitutes harassment.").
- ²⁶ Dear Colleague Letter, *supra* note 17, at 2.
- ²⁷ *Davis*, 546 U.S. at 644 (a school not engaging directly in harassment can only be liable if its "deliberate indifference subjects its students to harassment") (quotation marks and brackets omitted).
- ²⁸ Letter from Russlynn Ali, Asst. Sec'y for Civil Rights, U.S. Dep't of Educ., to Francisco M. Negron, Jr., General Counsel, Nat'l School Boards Ass'n of March 25, 2011, at 4.
- ²⁹ Prepared Testimony of Dr. John C. Eastman Before the U.S. Commission on Civil Rights at 4 (May 13, 2011) (emphasis supplied), available at <http://www.eusccr.com/7.%20John%20Eastman,%20Chapman%20University%20School%20of%20Law.pdf>.
- ³⁰ See, e.g., *Cuomo v. Clearing House Ass'n*, 129 S. Ct. 2710, 2721 (2009) (Office of the Comptroller of the Currency regulation interpreting the National Bank Act was unreasonable to extent it prohibited state attorney general from suing a national bank to enforce a state law, and thus, was not entitled to deference under *Chevron*).
- ³¹ Although we believe OCR's liability standard would not be upheld by the Supreme Court or most other appellate tribunals where the matter was fairly presented, few school districts can risk losing all federal funding pending

the outcome of a court challenge that may never reach the High Court. Moreover, casual or erroneous deference to OCR's position is certainly possible, even probable, in some lower courts. See Negron testimony, *supra* note 20.

³² *Indicta*, *Gebser* says that ED could require school districts to have a grievance procedure and publish a notice of anti-discrimination on the basis of sex. The Court states: "Agencies generally have authority to promulgate and enforce requirements that effectuate the statute's anti-discrimination mandate, . . . even if those requirements do not purport to represent a definition of discrimination under the statute." *Gebser*, 524 U.S. 274, 292 (1989). But such enforcement requirements mentioned in *Gebser* do not change or alter the definition of discrimination in the statute; they merely supplement its enforcement, as is the case with reporting and record-keeping requirements. OCR's Dear Colleague Letter attempts to fundamentally change the definition of discrimination.

³³ See Report at 64 (quoting Letter from Russlynn Ali to Francisco Negron, *supra* note 28, at 4) (emphasis supplied).

³⁴ See Report at 63.

³⁵ See *id.* at 68.

³⁶ *Id.* at 69. The Commission noted inconsistencies in OCR's legal standards and passed a recommendation that ED should "strive to use consistent language when it articulates legal standards," but rejected an amendment to the recommendation that ED's guidance should also be "based on appropriate legal authorities." Commissioners Gaziano, Heriot, and Kirsanow voted for this important and neutrally-worded amendment. Commissioners Castro, Thernstrom, Yaki, and Achtenberg voted against it. See Commission Transcript at 58-59 (Aug. 12, 2011).

³⁷ We did not support the report's recommendation number five in its current form because we have reason to believe OCR's view of the First Amendment issues is erroneous, and its evaluation of the implications of its guidance document on protected speech is possibly even disingenuous, as this section of our statement documents. Thus, what the Commission acknowledges as serious First Amendment problems (or at least concerns) created by OCR's letter are not likely to be cured by further "guidance" from that Office. Proper guidance surely is needed, but it may have to come from the courts or from other officials who are more sensitive to the First Amendment and less concerned about the reach of OCR's power to regulate school conduct and student speech with broad, over-inclusive language.

³⁸ Briefing Transcript, *supra* note 5, at 13 (Ali Testimony).

³⁹ Public Comment of Neal McCluskey, Assoc. Dir., Ctr. For Educ. Freedom, Cato Inst., at 1 *available at* <http://www.eusccr.com/28.%20Neal%20McCluskey,%20Cato%20Institute.pdf>. See also *id.* at 3-5 (for a more extensive discussion of the First Amendment issues in play, the catch-22 position schools are put in by ED's guidance and why zero-tolerance policies are inadvisable).

⁴⁰ The temptation to "engage in censorship of some students to benefit others" will be strong. Statement of Hiram Sasser, III, Dir. of Litigation, Liberty Inst., at 14 (May 13, 2011), *available at* <http://www.eusccr.com/11.%20Hiram%20Sasser,%20III,%20Liberty%20Institute.pdf> [hereinafter Sasser Statement]. "[B]ut the cause of freedom is never advanced by selective censorship of those messages with which the government disagrees." *Id.* at 15.

⁴¹ For example, we argued in our May 31, 2011 comments on the first draft of the report that the First Amendment concerns relating to the regulation of "cyber-bullying" be discussed in the Section that addresses why some people want to regulate it. Instead, the alleged harm associated with cyber-bullying is discussed in Section 2, but the First Amendment concerns associated with regulating it are confined to the last few pages of the report. Our discussion of the regulatory concerns is below.

⁴² *Tinker v. Des Moines Indep. Sch. Dist.*, 393 U.S. 503, 513 (1969). Note that the school's "undifferentiated fear or apprehension of disturbance is not enough to overcome the right of freedom of expression." Sasser Statement, *supra* note 40, at 4 (citing *Tinker*, 393 U.S. at 508). Likewise, the fact that someone is offended by the viewpoint expressed by the speech is also not sufficient to overcome the freedom of expression. See Statement of Eugene Volokh, Prof. of Law, Univ. of Cal., L.A., at 6 (May 13, 2011), *available at* <http://www.eusccr.com/27.%20Eugene%20Volokh,%20UCLA%20School%20of%20Law.pdf> [hereinafter Volokh Statement].

⁴³ *Bethel Sch. Dist. No. 403 v. Fraser*, 478 U.S. 675, 684 (1986).

⁴⁴ *Morse v. Frederick*, 551 U.S. 393, 397 (2007).

⁴⁵ Volokh Statement, *supra* note 42, at 6.

⁴⁶ "Public schools must not merely teach abstract principles of good citizenship, they must also serve as controlled laboratories for students to responsibly practice their constitutional freedoms. '[S]chools must teach *by example* the shared values of a civilized social order.'" Brief of Amicus Curiae Claremont Inst. at 3-4, *Morgan v. Swanson*, 628 F.3d 705 (5th Cir. 2007) (No. 09-40373) (citing *Fraser*, 478 U.S. at 683)).

- ⁴⁷ See *Saxe v. State College Area Sch. Dists.*, 240 F.3d 200, 209-210 (3d Cir. 2001) (in which the court held that "harassing" or "discriminatory" speech, however evil or offensive, is not categorically denied First Amendment protection, thereby invalidating a school district's anti-harassment policy as unconstitutionally overbroad for its impact on protected speech).
- ⁴⁸ See, e.g., *Snyder v. Phelps*, 131 S. Ct. 1207, 1219 (2011) (holding that the offensive speech of picketers near a military funeral could not be prohibited based upon the "viewpoint of the message conveyed").
- ⁴⁹ "Minors enjoy the protection of the First Amendment." *McConnell v. F.E.C.*, 540 U.S. 93, 231 (2003).
- ⁵⁰ The Court has rejected such proposals because, "[a]fter all, much political and religious speech might be perceived as offensive to some." *Morse*, 551 U.S. at 409. See also *Texas v. Johnson*, 491 U.S. 397, 414 (1989) ("If there is a bedrock principle underlying the First Amendment, it is that the government may not prohibit the expression of an idea simply because society finds the idea offensive or disagreeable.").
- ⁵¹ See generally Volokh Statement, *supra* note 42, at 3; Briefing Transcript, *supra* note 5, at 264, 306 (Volokh Testimony) (for a discussion of the specific First Amendment problems related to school regulation of "cyberbullying").
- ⁵² Report at 81 (citing Public Comment of Lambda Legal at 6-9)). See also Briefing Transcript, *supra* note 5, at 142 (Comments of Commissioner Yaki).
- ⁵³ See Report at 81-82 (citing Briefing Testimony of panelists Eliza Byard, Gregory Herek and Ilan Meyer).
- ⁵⁴ *Id.*
- ⁵⁵ Briefing Transcript, *supra* note 5, at 262 (Volokh Testimony).
- ⁵⁶ For a discussion of Professor Volokh's arguments that ED's guidance really is in large measure about speech, see the report at 82-83. Summarized briefly, indicators that the guidance does implicate constitutionally-protected speech include: (1) the over-breadth of the Dear Colleague Letter's definition of "harassment" to include "verbal acts," i.e., speech including name-calling and graphic or written statements; (2) its lack of requirement that "harassment" be directed at a specific target or involve repeated incidents—the Dear Colleague Letter is not limited to personal insults that go to a particular person and could include general statements; (3) the fact that ED's less stringent "sufficiently severe, pervasive or persistent" standard means that schools can now be liable for mere isolated one-offs, giving them an incentive to restrict speech; (4) the policy's reach, which purports to hold schools responsible for speech created off-campus (such as cyber-bullying) and suggesting that students could be punishable for such speech throughout the entirety of their school lives (what Volokh calls "24/7 control of student speech"); (5) the fact that the guidance goes beyond personal insults to reach even gossip; and (6) the fact that the Dear Colleague Letter may reach even criticism of religion or homosexuality based on the theory that such speech, if severe, pervasive or persistent enough, creates an offensive or abusive environment.
- ⁵⁷ Report at 85 (quoting Public Comment of Stuart Biegel at 4) (noting that the Seventh Circuit has "rejected the notion that First Amendment absolutist arguments should be controlling in a K-12 education setting").
- ⁵⁸ 627 F.3d 170, 176 (5th Cir.) (internal quotation marks omitted), *reh'g en banc granted*, 628 F.3d 705 (5th Cir. 2010).
- ⁵⁹ *West Virginia State Bd. of Educ. v. Barnette*, 319 U.S. 624 (1943). Former U.S. Solicitor General and D.C. Circuit Court of Appeals Judge Ken Starr was retained by the very same Barnett sisters who prevailed in their First Amendment case before the Supreme Court in 1943 to file a brief in the *Morgan* case to help convince these school officials that elementary school children are protected under the First Amendment's guarantee of free speech and that they may not discriminate against religious viewpoints. Brief for *Amici Curiae* Gathie Barnett Edmonds and Marie Barnett Snodgrass, 627 F.3d 170 (5th Cir.) *reh'g en banc granted*, 628 F.3d 705 (5th Cir. 2010) (No. 09-40373). (The Supreme Court case caption does not match the names of the Barnett sisters because the courts misspelled their family surname during the litigation. *Id.* at 2 n.1.) See also the brief authored by former U.S. Solicitor General Paul Clement and Liberty Institute lawyers on behalf of the school children in *Morgan*, making similar legal points as well as describing the school officials' outrageous actions in violating student speech rights. Supplemental En Banc Brief of Appellees, *id.*
- ⁶⁰ *Tinker v. Des Moines Indep. Cmty. Sch. Dist.*, 393 U.S. 503, 506 (1969).
- ⁶¹ Statement of Francisco M. Negron, Jr., General Counsel, National School Boards Association at 4-5 (May 13, 2011), available at <http://www.eusccr.com/24.%20Francisco%20Negron,%20National%20School%20Boards%20Association.pdf>.
- ⁶² *Id.* at 4.
- ⁶³ "But if every instance implicates a federal right, educators will have no choice but to take formal steps in even the most mundane cases to avoid agency liability and prepare for a legal defense." *Id.* at 9.
- ⁶⁴ Briefing Transcript, *supra* note 5, at 263 (Volokh Testimony).

- ⁶⁵ See, e.g., *Harper v. Poway Unified Sch. Dist.*, 445 F.3d 1166 (9th Cir. 2006), *vacated as moot*, 549 U.S. 1262 (2007) (mem.) (case involving whether school could properly prohibit a student from wearing a T-shirt expressing his views on homosexuality).
- ⁶⁶ As our colleague Commissioner Heriot notes in her dissenting statement, there is no federal agency charged with safeguarding students' First Amendment rights. There is at least one private group—the Foundation for Individual Rights in Education (FIRE)—that works on such issues, but they primarily confine their efforts to infringements on individual rights at colleges and universities. Given this asymmetry of incentives, many schools may be tempted to over-reach in the direction of avoiding litigation over bullying than in the direction of avoiding litigation over First Amendment concerns.

- ⁷⁸ *Davis*, 526 U.S. at 657-58 (Kennedy, J., dissenting).
- ⁷⁹ Nor do some of our witnesses. See, e.g., Briefing Transcript, *supra* note 5, at 293-94 (Volokh Testimony) ("[O]ne thing that troubles me about a lot of this discussion including the Dear Colleague Letter is the sense that there's sort of denial going on. That there really isn't any speech issue in play. Sometimes the claim is 'this is conduct, not speech,' even though the conduct consists of verbal acts which is another way of saying speech. Sometimes the claim is 'it's harassment and not speech,' even though if you label speech 'sedition' or 'harassment' or 'intentional infliction of emotional distress,' that doesn't strip it of constitutional protection.").

- ⁸⁴ Dear Colleague Letter, *supra* note 17, at 8 (emphasis supplied).
- ⁸⁵ Prepared Testimony of Roger Clegg, President and General Counsel, Center for Equal Opportunity, Before the U.S. Commission on Civil Rights at 7 (May 13, 2011), *available at* <http://www.eusccr.com/6.%20Roger%20Clegg,%20Center%20for%20Equal%20Opportunity.pdf>.
- ⁸⁶ See, e.g., *Pratt v. Indian River Cent. Sch. Dist.*, 2011 WL 1204804, *11 (N.D.N.Y. Mar. 29, 2011) ("[H]arassment based on nonconformity with sex stereotypes is a legally cognizable claim under Title IX."); *Riccio v. New Haven Bd. of Educ.*, 467 F. Supp. 2d 219, 226 (D. Conn. 2006) ("If not for her status as a female, a reasonable trier of fact could conclude that Andree would not have been called the offending slurs. As such, Andree, a female student, targeted by other female students and called a variety of pejorative epithets, including ones implying that she is a female homosexual, has established a genuine issue of fact as to whether this harassment amounts to gender-based discrimination, actionable under Title IX."); *Montgomery v. Independent Sch. Dist. No. 709*, 109 F. Supp. 2d 1081, 1092 (D. Minn. 2000) ("[B]y pleading facts from which a reasonable fact-finder could infer that he suffered harassment due to his failure to meet masculine stereotypes, plaintiff has stated a cognizable claim under Title IX.").
- ⁸⁷ The report cites one case where the defendant school board argued that the statements in question were about sexual orientation and not gender, but, as the report notes, the court rejected this argument. Report at 55 & n.283 (citing *Riccio*, 467 F. Supp. 2d at 225).
- ⁸⁸ Commissioners Castro, Thernstrom, Yaki, and Achtenberg voted against adding the clarifying language. See Commission Transcript at 31 (Aug. 12, 2011).
- ⁸⁹ The Safe Schools Improvement Act, S. 506, defines harassment even more broadly than OCR—as "conduct . . . that adversely affects the ability of one or more students to participate or benefit from the school's educational programs or activities . . ." The phrase "adversely affects" is broader than OCR's phrase "interfere with or

limit," which in turn far exceeds the "deprive" standard in *Davis*. The Act would require states to collect and report on "the incidence, prevalence, age of onset, perception of health risk, and perception of social disapproval of bullying and harassment by youth in elementary schools and secondary schools." It would also require local school boards to adopt anti-bullying policies and procedures, including formalized, written grievance procedures. The Student Non-Discrimination Act, H.R. 998, likewise goes beyond putting sexual orientation and gender identity on the same footing as race, color, national origin, sex, or disability in the federal anti-discrimination laws. The Act also prohibits harassment based on "the actual or perceived sexual orientation or gender identity of a person or persons with whom a student associates or has associated," while adopting OCR's broad standard of what constitutes harassment. Such an expansion of prohibited harassment in federal law would certainly open the door to more litigation against school districts.

⁹⁰ We also join Commissioner Heriot's regret that the new majority also canceled: (1) the ongoing investigation into DOJ's handling of and ultimate dismissal of most of its New Black Panther Party lawsuit, and (2) the original research into whether certain colleges and universities were discriminating against women in admission. See Heriot Dissenting Statement at 185 n.14.

⁹¹ Castro Statement at 91.

⁹² Castro Statement at 92. See also Yaki Statement at 217 (stating, without the least explanation, that the protections he favors "must be uniform"); Achtenberg Statement at 121: "[T]he lack of consistency among state laws demonstrates the need for federal legal protections." With due respect, it demonstrates nothing of the kind.

⁹³ See *supra* note 6.

⁹⁴ See Commissioner Heriot's Statement at 189-90. See also, e.g., *Outcry Spurs School to Lift Boy's Suspension for Kissing*, ST. LOUIS POST-DISPATCH, Oct. 3, 1996 (6-year-old North Carolina boy suspended for kissing girl on cheek); JuJu Chang et al., *First Grader Labeled a Sexual Harasser*, ABC NEWS, April 4, 2008, available at <http://abcnews.go.com/GMA/AsSeenOnGMA/story?id=4585388>. During the 2005-06 school year in the state of Maryland, 28 kindergarteners were suspended for "sex offenses, including 15 for sexual harassment." Yvonne Bynoe, *No Hugs Allowed*, WASH. POST, Oct. 22, 2007.

⁹⁵ The Antioch College policy still states: "Consent is defined as the act of willingly and verbally agreeing to engage in specific sexual conduct. . . . Consent is required each and every time there is sexual activity." Eugene Volokh, GETTYSBURG COLLEGE JOINS ANTIOCH COLLEGE, THE VOLOKH CONSPIRACY, May 11, 2006 (quoting Antioch College policy) (emphasis added), available at <http://volokh.com/posts/1147374096.shtml>; see also FIRE, *Gettysburg College: Hug at Your Own Risk*, May 11, 2006 ("Under the [Gettysburg College] policy, 'consent' to sexual interaction is defined as 'the act of willingly and verbally agreeing (for example, by stating 'yes') to engage in specific sexual conduct. If either person at any point in a sexual encounter does not give continuing and active consent, all sexual contact must cease, even if consent was given earlier. . . . The policy's broad definition of sexual interaction includes not only sex acts but also 'brushing, touching, grabbing, pinching, patting, hugging, and kissing.'"). See also Sandy Hingston, *The New Rules of College Sex*, PHILADELPHIA MAG., Sept. 2011. Justice Kennedy's dissent in *Davis* cites a 1994 sexual harassment manual which suggests that a comment as mild as "You look nice" from one student to another could be sexual harassment, depending on the "tone of voice," how the student looks at the other student, and who else is around. 526 U.S. at 326.

⁹⁶ Report at 10 n. 42 (citing American Association of University Women, *Hostile Hallways: Bullying, Teasing, and Sexual Harassment in School 20-21* (2001) (unwelcome "flirting" is sexual harassment)).

⁹⁷ Briefing Transcript at 307 (May 13, 2011).

⁹⁸ In December 2009 at a high school in South Philadelphia, African-American students attacked Asian American students, sending 13 of them to the hospital, despite repeated complaints to school officials and requests for protection from the Asian-American students, which went largely unheeded. Report at 13; see also Krissah Thompson, *Justice reaches pact with Philadelphia schools in '09 attacks on Asian American students*, WASH. POST, Dec. 15, 2010.

⁹⁹ In March 2010, Secretary of Education Arne Duncan announced that ED would initiate a number of compliance reviews to examine, among other things, whether schools are disciplining certain protected categories of students too much and others too little. For example, OCR proposes to use "disparate impact" theory and statistical analysis to determine whether a given school is disciplining blacks more than their expected ratio, or perhaps, disciplining boys more than girls of the same age. A finding of discrimination might follow. The Commission questioned OCR at a briefing on the topic early this year. See Testimony of Ricardo Soto, Office for Civil Rights, U.S. Dep't of Education Before the U.S. Commission on Civil Rights (Feb. 11, 2011). In contrast to OCR, several of the teachers and local authorities who also testified shared our view that the right amount of discipline was what the students individually deserved, regardless of their race or gender

and whether or not their protected group had reached its discipline quotient for the week. Indeed, we expressed concern OCR's policy could have serious negative consequences, harming minority students in classes with a number of disruptive classmates who are not disciplined enough because federal bureaucrats convince teachers they will pay a price if their disciplinary tally sheet doesn't look right. Briefing Transcript on Disparate Impact in School Discipline at 113-15 (Feb. 11, 2011).

¹⁰⁰ Hiram Sasser of the Liberty Institute in both his written and oral testimony quoted the following passage from the Supreme Court's opinion in *Tinker*: Any departure from absolute regimentation may cause trouble. Any variation from the majority's opinion may inspire fear. Any word spoken, in class, in the lunchroom, or on the campus, that deviates from the views of another person may start an argument or cause a disturbance. But our Constitution says we must take this risk, *Terminiello v. Chicago*, 337 U.S. 1 (1949); and our history says that it is this sort of hazardous freedom—this kind of openness—that is the basis of our national strength and of the independence and vigor of Americans who grow up and live in this relatively permissive, often disputatious, society.

Written Statement of Hiram Sasser at 16-17 (quoting *Tinker v. Des Moines Indep. Cmty. Sch. Dist.*, 393 U.S. 503, 508-09 (1969)).

¹²² Lisa M. Diamond, *New Paradigms for Research on Heterosexual and Sexual-Minority Development*, 32 Journal of Clinical Child and Adolescent Psychology 490, 495 (2003) ("[A]lthough gay-related stress might be the most salient mechanism through which sexual-minority status influences adolescent development, it is not necessarily the most predominant or important.").

¹²³ Achtenberg Statement at 110 (citing inst. of med. of the nat'l academies, the health of lesbian, gay, bisexual, and transgender people 32 (2011) (emphasis added)).

¹²⁴ Achtenberg Statement at 109-12 (internal quotation marks omitted).

¹²⁵ Commissioner Heriot's dissenting statement and rebuttal discusses various reasons why the "negative outcomes" gay youth appear to suffer may more likely result from causes besides peer bullying.

- ¹²⁶ See, e.g., *Missouri v. Jenks*, 515 U.S. 70, 121 (1995) (Rehnquist, C.J.) ("Psychological injury or benefit is irrelevant to the question of whether state actors have engaged in intentional discrimination . . ."). Likewise, it has no bearing on whether school officials have shown deliberate indifference to "severe, pervasive and *objectively* offensive" gender-based harassment of students in violation of Title IX. See *Davis*, 526 U.S. at 650 (emphasis supplied). Thus, the volumes of conflicting and potentially misleading social science research on a possible underlying psychological predisposition to bullying are wholly irrelevant to Title IX enforcement decisions.
- ¹²⁷ *Davis*, 526 U.S. at 646.
- ¹²⁸ The policy's implementation is currently being challenged in court. To our knowledge, the Commission neither requested nor received testimony or other information from the school district on its policy. Only one side of the issue was thus presented at our briefing, from a parent who seems to have mischaracterized the district's written policies. Had we known that the district's policy was going to be raised at the briefing, we would have urged the Commission to invite a representative from the district to testify. But as discussed in this section, we have reviewed the court complaint and other material on both sides of this issue. The curriculum policy itself and the school district's anti-bullying policies are all contained in publicly available documents.

End Notes for Dissenting Statement of Commissioner Gail Heriot, with Which Commissioners Peter Kirsanow and Todd Gaziano Concur

- ¹ The brief discussion of the objections to the policy is contained almost exclusively in the last Section of the report.
- ² I agree with my colleagues Commissioners Todd Gaziano and Peter Kirsanow that none of the empirical studies on bullying cited in the report is relevant to the issues before the Commission. See Joint Dissent and Rebuttal of Commissioners Gaziano and Kirsanow. These studies do not show that the kind of bullying for which school districts can be held legally accountable for is widespread. Moreover, they do not show that school districts are failing to respond to the problem. Some of these polls are unscientific internet questionnaires that are far from random samples of students. See GLSEN Survey 2009. One would have to expect that victims of bullies are more interested in visiting the GLSEN web site and responding to such polls. All appear to use definitions of bullying or harassment that are overbroad and include activity that would be protected under the First Amendment or that would more properly be classed as tactlessness. In some cases, eye-rolling or engaging in gossip is classed as bullying. See Report at 3. It would have been useful to analyze each of these studies and discuss exactly what they do or do not establish. But there was no time for such meticulous work. The first draft of the report had to be finished one week after the Commission held its first and only hearing on the matter on May 13, 2011. See Transcript of Commission Meeting 10 (August 12, 2011).
- ³ 42 U.S.C. 1975(c)(1): "The Commission shall submit to the President and Congress at least one report annually that monitors Federal civil rights enforcement efforts in the United States."
- ⁴ See Mary Frances Berry, Request for the U.S. Commission on Civil Rights, Hearing Before the Subcommittee on Civil and Constitutional Rights of the Committee on the Judiciary, House of Representatives, 103 Cong., 2d Sess. (February 9, 1994) ("We are a watchdog over the effectiveness of federal civil rights enforcement"); Mary Frances Berry Exits Civil Rights Commission; Gerald Reynolds Picked as New Chairman, *Jet* (December 27, 2004/January 3, 2005) ("Berry, who at times has been at odds with five presidents over civil rights issues since 1980, once reportedly said, 'If we don't have people irritated, we're not doing our job We're the watchdog that bites you on the leg, keeps tugging at you'").
- In theory at least, the fact that the Commission's eight members are part-time, usually have primary jobs outside the federal bureaucracy and have some expertise in civil rights, means that we can be free from the bias that sometimes hinders the efforts of federal officials assessing the performance of other federal officials. We need not (and should not) be beholden to anyone.

- ⁵ Time for rebuttals was also reduced from the usual 30 days to 21 days. While it is understandable that Chairman Castro would be concerned about getting the final report out by end of the fiscal year, the hurry was purely a result of the Commission's decision to switch topics halfway through the year.
- ⁶ The term "*cy pres*" comes from the French phrase "*cy pres comme possible*" or "as near as possible." It traditionally referred to a doctrine in trusts and estates law. When a testator attempts to create a charitable trust that will provide funds to a non-profit entity that no longer exists or for a purpose that can no longer be carried out, a court may order or allow those funds to be applied to a similar non-profit entity or for a similar purpose instead. Edith L. Fisch, *The Cy Pres Doctrine in the United States* 1 (1950). More recently, the term has been used to describe the practice described by Byron York in *Justice Department Steers Money to Favored Groups* under which non-profit organizations are awarded any unclaimed settlement funds or court-ordered damages in a class action or similar proceeding. Another term sometimes used in this context is "fluid class remedies."
- ⁷ Byron York, *Justice Department Steers Money to Favored Groups*, *Washington Examiner* (August 5, 2010).
- ⁸ The project was later expanded to include the Equal Employment Opportunity Commission (EEOC) and private civil rights class actions.
- ⁹ Another way to deal with the problem is to over-compensate those victims who do claim funds. For example, if 20,000 victims are expected, but only 10,000 actually present themselves, each one with an injury valued at \$10, each could receive \$20.
- ¹⁰ Martin H. Redish, Peter Julian & Samantha Zyontz, *Cy Pres Relief and the Pathologies of the Modern Class Action: A Normative and Empirical Analysis*, 62 Fla. L. Rev. 617 (2010) (stating that the doctrine of *cy pres* in the context of class action litigation "richly deserves" "scathing scholarly critique"); John H. Beisner, Jessica Davidson Miller & Jordan H. Schwartz, *Cy Pres: A Not So Charitable Contribution to Class Action Practice*, U.S. Chamber Institute for Legal Reform 19 (October 2010) ("[T]he expansion of *cy pres* into the class action context has generated significant conflict of interest concerns with respect to plaintiffs' attorneys, judges and defendants"); Theodore H. Frank, *Cy Pres Settlements*, *Class Action Watch* (March 2008) (stating that the use of *cy pres* in the class action context creates "clear conflicts of interest"). See also Adam Liptak, *Doling Out Other People's Money*, *The New York Times* (November 26, 2007) (discussing, among other things, the efforts of New York University law professor Samuel Issacharoff to rein in this practice by issuing guidelines through the American Law Institute).
- ¹¹ Redish, Julian and Zyontz, 62 Fla L. Rev. at 665.
- ¹² Adam Liptak, *Doling Out Other People's Money*, *The New York Times* (November 26, 2007) ("[The use of the *cy pres* doctrine in private class actions] gives rise to this unbelievable world that I was shocked to learn about, and I'm not easily shocked in litigation," Professor [Samuel] Issacharoff [of New York University Law School] said. "Charities hire lawyers to go lobby the judge for the extra money.").
- ¹³ In addition, Commissioner Arlan Melendez was replaced by Dina Titus and the seat held by Commissioner Michael Yaki was briefly unoccupied. Both Melendez and Titus were appointed on the recommendation of Senate Democratic Leader Harry Reid. Michael Yaki was later re-appointed on the recommendation of House Democratic Leader Nancy Pelosi.
- ¹⁴ See Statement of Chairman Martin R. Castro at 90 (quoting President Barack Obama at the White House Summit on Bullying Prevention on March 10, 2011).
The newly-constituted Commission also cancelled two other on-going investigations—one into discrimination against women in higher education and the other into race-neutral enforcement of civil rights laws at the Department of Justice, a project which began as an investigation of the Department of Justice's handling of a lawsuit against the New Black Panther Party for voter and poll worker intimidation. What all three projects had in common was each contained elements that were critical or potentially critical of the current Administration's policies. Put differently, in each case, the Commission was fulfilling its mission to be a civil rights watchdog. See *supra* at n. 4. For a discussion of the termination of the sex discrimination investigation, see Gail Heriot & Alison Somin, *Affirmative Action for Men?: Strange Silences and Strange Bed Fellows in the Public Debate Over Discrimination Against Women in College Admissions*, Engage (2011) (forthcoming).
- ¹⁵ The vote to terminate the investigation was 4 to 3. Voting in favor of termination were Chairman Castro (appointed by President Obama), Commissioner Roberta Achtenberg (appointed by President Obama), Commissioner Dina Titus (appointed upon recommendation of Senate Democratic Leader Reid) and Vice Chair Thernstrom (appointed by President Bush, but who has caucused with Democrats for the past two years and votes with them except when it is clear her vote will not affect the outcome. I know of only one very minor exception to this rule since the Commission was re-constituted at the beginning of 2011). Voting against termination were Commissioner Peter Kirsanow (appointed by President Bush), Commissioner Todd Gaziano (appointed on

recommendation of House Republican Leader Boehner), and me (appointed on recommendation of Senate Republican Leader McConnell).

Believing that the Civil Rights Division might be eager to demonstrate that its staff members had never funneled funds to an organization with which they had some personal relationship, that it had not become lackadaisical about finding the real victims of civil rights violations, and that its procedures for selecting the recipients of funds were designed to avoid the potential for conflicts of interest, my special assistant, with my encouragement and cooperation, sent the Department of Justice a Freedom of Information Act request on June 10, 2010. DOJ acknowledged receipt of the request on June 21. No documents have been produced to date.

A similar request was sent to the EEOC on June 10, 2011. An acknowledgment was sent on June 17. On August 17, my special assistant received a letter stating that the EEOC estimated that costs of searching for responsive documents would be over \$5,000. She and I are waiting for a response to her request for a fee waiver.

¹⁶ Although Section 3 of the report purports to offer new information, what it there sheds no useful light on the question of whether the Department of Education is doing its job properly or on any other significant question. What it does is provide charts and counts for the sake of charts and counts. As my colleagues Commissioners Todd Gaziano and Peter Kirsanow point out in their Joint Dissent, it is unclear how many of the complaints counted in this Section actually involve student to student harassment (as opposed to alleged harassment of a student by a teacher or other school official). There is also no attempt to assess how many of the voluntary resolution agreements discussed in that Section were actually meritorious. See Joint Dissent of Commissioners Gaziano and Kirsanow at 132-33.

¹⁷ Certainly, there are times when coordination at the national level is crucial. But no such coordination is necessary for dealing with bullies. And even if it were necessary, the federal government is not offering it. Rather, it offers fragmentation. Federal law confers jurisdiction to act on the Department of Education only when bullying is a manifestation of race, sex, national origin, or disability discrimination. There are ways in which bullying on these grounds may differ from bullying on other grounds. But it is unclear why anyone would want a school to have one method for responding to a bully who is harassing his victim because the victim is nearsighted or his parents are from Ukraine and another one for when the bully is motivated by the fact that his victim is homely, nerdy or socially awkward.

¹⁸ While the Department of Education uses the word "bullying" in addition to "harassment" in describing its policy, the policy is essentially a harassment policy and draws on court decisions relating to sexual harassment for its justification. See Dear Colleague Letter of October 26, 2010 from Russlynn Ali, Assistant Secretary for Civil Rights, U.S. Department of Education.

A few words on how sexual harassment law in connection with Title VII has driven harassment law generally are in order: In 1964, when both Title VI (prohibiting race, color and national origin discrimination in federally-assisted programs) and Title VII (prohibiting race, color, sex, religion and national origin discrimination in public and private employment) were passed as part of the Civil Rights Act of 1964, the latter was considered much more significant. An entirely new federal agency—the EEOC—was created to administer the law, and it was clear from the beginning that a private cause of action would lie. Deputy Attorney General Nicholas deBelleville Katzenbach estimated in two letters to Emmanuel Celler, Chairman of the Committee on the Judiciary of the House of Representatives, both dated February 6, 1964, that Title VI would require only three employees and a budget of \$62,510. Title IV (school desegregation) on the other hand was estimated to require 150 employees and a budget of \$10,752,560, while Title VII was expected to require 155 employees and a budget of \$3,875,000. Title IX, part of the Educational Amendments Act of 1972, prohibiting sex discrimination by educational institutions receiving federal financial assistance, was passed eight years later.

In 1964, the kind of race and sex discrimination in employment that people most readily thought of was not subtle. Newspapers in the South routinely categorized their "Help Wanted" ads as "Help Wanted—White" and "Help Wanted – Colored," and "Help Wanted—Male" and "Help Wanted—Female" ads were common almost everywhere. Nevertheless, Title VII's text does not prohibit only gross discrimination; it prohibits discrimination. When confronted with the question of whether Title VII prohibits an employer from maintaining a working environment that is so hostile to a particular race (or to one sex) that few members of that group would be willing to expose themselves to it, the Supreme Court and other courts rightly ruled that it may. See *Meritor Savings Bank v. Vinson*, 477 U.S. 57 (1986)(sex); *Rogers v. EEOC*, 454 F.2d 234 (5th Cir. 1971), cert. denied, 406 U.S. 957 (1972)(race).

This did not result in an immediate explosion of cases. At the time, Title VII plaintiffs could sue for back pay or for an injunction requiring that the offending conduct stop. But they could not sue for emotional distress damages. As a result, an employee who had been harassed would be unlikely to sue unless things were so bad that she had quit or the employer refused to rectify something that mattered to her enough to get an injunction.

Small grievances—both valid and invalid—were more likely to be left to the ordinary give and take of the workplace. All this changed in 1991 when Title VII was amended to allow money damages (instead of just back pay) and punitive damages. Changes in remedies frequently lead to profound changes in the way the substantive law is interpreted and applied. It was in 1991 that journalists (and even comedians) began to make fun of some of the comparatively trivial cases that employers had to contend with. See, e.g., Nat Hentoff, *Sexually Harassed by Francisco Goya*, Wash. Post. (Dec. 27, 1991)(copy of Goya's Naked Maja removed from classroom where it had hung for years after professor said it harassed her).

Meanwhile, as sexual harassment prevention was becoming part of the zeitgeist, cases brought under Title IX, which covers educational institutions receiving federal funds, began to be filed too. See *Franklin v. Gwinnett County Public Schools*, 503 U.S. 60 (1992)(holding that a case for money damages may be brought under Title IX for teacher's sexual harassment of student). Like the Title VII cases, once monetary damages became available, some of the Title IX lawsuits were trivial. See, e.g., *Nevermore for Poe Film*, Lawsuit Says, San Francisco Examiner (Aug. 30, 1994)(teenager sues for sexual harassment under Title IX after English teacher showed movie based on Edgar Allan Poe's classic short story "The Pit and the Pendulum").

The Department of Education was very much part of the zeitgeist that availability of money damages had helped create. On March 13, 1997, it upped the ante by issuing *Sexual Harassment Guidance: Harassment of Students by School Employees, Other Students or Third Parties*. That guidance made it clear that a school that did not come down hard on what the Department of Education considered sexual harassment might find itself the subject of a federal investigation. In the years that followed, the zero tolerance rules enforced against tiny tots began to appear. See also *Sexual Harassment Panda*, South Park Episode No. 37 (July 7, 1999)(comic treatment of an elementary school's sexual harassment policy).

In *Gebser v. Lago Vista Independent School District*, 524 U.S. 274 (1998), the Supreme Court gave much-needed clarification to the law by holding that damages may not be recovered for a case of teacher-on-student sexual harassment unless a school district official with authority to take corrective action had actual notice of the harassment and was deliberately indifferent. See *Burlington Industries, Inc. v. Ellerth*, 524 U.S. 742 (1998)(imposing similar requirements in Title VII case).

In 2000, in the case of *Davis v. Monroe County Board of Education*, 526 U.S. 629 (2000), the Supreme Court further clarified by holding that in addition to the limitations in *Gebser*, damages for student-on-student sexual harassment are available from the school district only when the harassment was so severe, pervasive and objectively offensive that it could be said to deprive the victim of access to the educational opportunities or benefits provided by the school."

In response to *Gebser* and *Davis*, the Department of Education was obliged to issue a new guidance in January of 2001, entitled *Revised Sexual Harassment Guidance: Harassment of Students by School Employees, Other Students, or Third Parties*.

I agree with my colleagues, Commissioners Gaziano and Kirsanow, that the current Dear Colleague Letter goes far beyond *Gebser* and *Davis* by making a school district responsible for (1) harassment/bullying not just that some responsible party knew about but that some responsible party should have known about; (2) student-on-student harassment/bullying that is not just "severe, pervasive *and* objectively offensive" but "severe, pervasive *or* persistent;" and (3) student-on-student harassment/bullying that "*interferes with or limits* a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school" instead of the Supreme Court's standard of harassment/bullying that "*deprives* the victims of access to educational opportunities or benefits provided by a school." (Emphasis supplied). See Joint Dissent of Commissioners Gaziano and Kirsanow at 139-45. Indeed, it appears to me that the letter goes beyond any fair reading of Title VI or Title IX.

²⁰ Juju Chang, Alisha Davis, Cole Kazdin and Olivia Sterns, First-Grader Labeled a Sexual Harasser: Has Zero-Tolerance for Sexual Harassment in Schools Gone Too Far?, ABC News (Feb. 19, 2009).

²¹ Yvonne Bynoe, Is that 4-Year-Old Really a Sex Offender?, The Washington Post (Oct. 21, 2007). According to the article, school spokeswoman Carol Mowen said, "It's important to understand a child may not realize that what he or she is doing may be considered sexual harassment, but if it fits under the definition, then it is, under the state's guidelines." These state guidelines were promulgated in an effort to comply with federal civil rights law.

²² Id.

²³ Gitika Ahuja, First-Grader Suspended for Sexual Harassment: Boy's Mother Says He's Too Young to Even Understand the Accusation, ABC News (February 9, 2006). The article reports: "In a statement, Brockton Superintendent of Schools Basan Nembirkow said the district takes 'all allegations of sexual harassment very seriously. An investigation is always conducted when reports of sexual harassment arise. Principals are trained

to handle these difficult situations and they are assisted, as needed, by the district's sexual harassment officer in handling each situation."

²⁵ Juju Chang, Alisha Davis, Cole Kazdin and Olivia Sterns, First-Grader Labeled a Sexual Harasser: Has Zero-Tolerance for Sexual Harassment in Schools Gone Too Far?, ABC News (Feb. 19, 2009).

²⁶ I have asked the Commission to look into this issue, but have so far been unsuccessful in persuading a majority of the commissioners to do so.

²⁷ 240 F.3d 200, 204, 206 (3d Cir. 2001).

²⁸ *Bethel School Dist. No. 403 v. Fraser*, 478 U.S. 675 (1986); *Tinker v. Des Moines Indep. School Dist.*, 398 U.S. 503 (1969); *Saxe v. State College Area School Dist.*, 240 F.3d 200 (3d Cir. 2001). Commissioner Yaki's Statement is devoted almost exclusively to the proposition that the Constitution sometimes permits and indeed sometimes requires that children be treated differently from adults. No one denies this—although the cases he cites for that proposition do not always stand for it. See, e.g. *Jacobson v. Massachusetts*, 197 U.S. 11 (1905) (upholding Massachusetts' compulsory vaccination law against an adult plaintiff). By the same token, however, no serious student of the law can deny that while the Supreme Court has recognized limits on the application of the First Amendment to school children, it has also recognized that school children have First Amendment rights at school and outside of school in the same cases. See *Tinker*, 393 U.S. at 506 ("It can hardly be argued that either students or teachers shed their constitutional rights to freedom of speech or expression at the schoolhouse gate."). Commissioner Yaki's Statement does not deal with this at all. Nor does it deal with the question of whether the Department of Education has or should exercise the authority to regulate public or private schools in the manner it purports to do in its Dear Colleague Letter.

²⁹ The only organization I know of that specializes in protecting the First Amendment and academic freedom rights of faculty and students on college and university campuses is the Foundation for Individual Rights in Education (FIRE). Although some of the cases that FIRE litigate may lead to judicial decisions that affect K-12 public schools, FIRE works primarily on safeguarding the individual rights of university students rather than on defending those of younger students. Sadly, its staff is also tiny. But see William Shakespeare, *Henry V*, act iv, scene iii (c. 1598).

³⁰ See, e.g. Jon B. Gould, *Speak No Evil: The Triumph of Hate Speech Regulation* (2005).

³¹ See, e.g., Mari Matsuda, Charles R. Lawrence III, Richard Delgado and Kimberle Williams Crenshaw, *Words that Wound: Critical Race Theory, Assaultive Speech and First Amendment* (1993) (advocating hate speech codes); Richard Delgado and Jean Stephancic, *Must We Defend Nazis?: Hate Speech, Pornography and the New First Amendment* (1999) (same).

Higher education is not the only place where serious First Amendment controversies have erupted in the last decade. Professor David E. Bernstein has written about the use of federal employment discrimination law to limit free expression in the workplace. See David E. Bernstein, *You Can't Say That!: The Growing Threat to Civil Liberties from Anti-Discrimination Laws* (2003) (discussing sexual harassment law's effect upon the workplace).

³² State anti-bullying initiatives may also have this effect. See Jonathan Saltzman, *Antibully Law May Face Free Speech Challenges*, *The Boston Globe* (May 4, 2010). That article stated:

[S]ome aspects of the law are so general that civil rights lawyers are concerned about how schools will apply it. The law, for example, defines one form of bullying as "repeated use" of a written, verbal, or physical act that "causes physical or emotional harm to the victim."

By that standard, said Gavi Wolfe, legislative counsel for the American Civil Liberties Union of Massachusetts, a student who calls another student "loser" twice on the school bus and hurts the youngster's feelings could qualify as a bully. A bus driver who heard the remarks would have to report them to school officials, who would then have to contact the parents of both children and take appropriate disciplinary action.

Harvey A. Silverglate, a well-known Boston civil rights lawyer, said, "School authorities are going to overreact, and we're going to have a firestorm of administrative actions against kids for saying this that are merely slightly unpleasant but do not qualify as bullying or harassment or any such thing."

³³ It has its costs, of course. Once such a bureaucracy is put in place, it is very difficult to dispense with it, even if the need for it diminishes. Such are the consequences of history.

³⁴ The case in South Philadelphia described at our briefing by Helen Gym of Asian Americans United may well be an example.

³⁵ Statement of Chairman Martin R. Castro at 90. It is useful to note that forty seven years ago, Chairman Castro could not have made a similar statement about the education issue of the day. It was not true that everyone wanted to ensure that African American students had the right to attend the same schools as their peers, regardless of race.

That is why federal intervention was useful: The Fourteenth Amendment was being flouted. There is nothing remotely analogous to the massive resistance to *Brown v. Board of Education* today. There have many disagreements about education policy, but there are no adults outside homes for the criminally insane who don't want all the nation's children to have a safe place to learn.

³⁶ Everyone's heart goes out to Ms. Aaberg, the mother of Justin Aaberg, the 15-year-old student from the Anoka High School in Anoka, Minnesota, who took his own life on July 9, 2010 during the summer vacation between his freshman and sophomore years. But when bereaved relatives testify before a commission about their grief, care must be taken to prevent the proceedings from degenerating into political theater. In our case one of our Commission members used Ms. Aaberg's testimony as a club to attempt to discourage one of our other witnesses—Francisco M. Negron, Jr., general counsel to the National School Boards Association—from testifying candidly. Mr. Negron was kind enough to inform us of the kinds of problems school boards face in trying to satisfy the federal mandate on bullying. Commissioner Yaki responded this way:

I'm going to be as civil as I possibly can. But it just seemed to me very difficult for me to listen to your testimony talking about the fear of lawsuits and plaintiffs' lawyers when you're talking about sitting next to someone who lost their son

And to talk about plaintiffs' lawyers and whatever is essentially saying, 'Well you know there's a price we have to pay and there's some cost benefit analysis that we have to do when it comes to how much a child's life is.' At least that's the way it came to me. I know that's not what you meant, but certainly the way it came out.

So my question to you is, you talk about the fact that there should be no federal mandates, because there should be local leadership. How do you explain [that] to Ms. Aaberg?

Tr. at 275-76.

This was not fair. Mr. Negron was given a difficult task—giving testimony directly after a mother had offered her story of the loss of her young son—and he fulfilled that task with tact and grace. Mr. Negron and the National School Boards Association are at least as concerned about the safety and welfare of children as Commission Yaki and the other members of the Commission. But among other things, Mr. Negron has a duty to try to ensure that school resources are not spent on unproductive bureaucratic red tape rather than on actual teaching and learning. Moreover, as Commissioner Yaki must surely know, the job of preventing suicide is not as easy as it was made to seem at our staged media event—complete with poster-sized photographs of smiling suicide victims on easels. Increased federal oversight is unlikely to do the trick. The next suicide in the Anoka-Hennepin School District may not be the victim of an anti-gay bully. Next time it may be a child who was wrongly accused of being a bully instead. Perhaps it will be a child who never did anything at all, but whom the true bullies accuse of wrongdoing just for the fun of it. Or perhaps it will be a child reared in a religious tradition that disapproves of homosexuality, but who has done nothing but decline to endorse it. History never repeats itself exactly. The next time might not be a suicide at all; instead it may be a fatal accident because some school district somewhere had its budget strained by the kind of litigation that Commissioner Yaki seems unconcerned about and hence was not able to keep its school buses properly maintained. It is a complicated world. And it will not be made better or less complicated by a federal bureaucracy attempting to accomplish through federal mandate that which cannot be accomplished that way.

Justin Aaberg's tragic suicide is very much part of that complicated world. Members of the Commission seem to assume that it was a direct result of school bullying. But immediately after his death, which occurred in July, between school sessions, WCCO, the CBS affiliate in Minnesota, reported that his friends told Ms. Aaberg that he "had recently broken up with his boyfriend."

<http://minnesota.cbslocal.com/health/glb.t.teen.suicide.2.1910636.html>. To be sure, they also reported to her that he had sometimes been bullied. But there is nothing in the article to link the suicide to either the break up or the bullying, and given that the suicide took place in the middle of the summer, it seems doubtful that the link between it and any bullying at school was direct and immediate. At best, it may have had an indirect link.

In her testimony, Ms. Aaberg related the two incidents that she knew of. First, more than a year prior to his death, two other students grabbed at his genitals in the hallway and taunted him saying, "You like that, don't you?" This incident had left young Justin crying, and his friends reported the incident to the school counselor. There is nothing in the Commission's record that makes it clear what, if anything, the counselor did about it. Ms. Aaberg was inclined to be critical of the counselor for failing to inform her of what happened. But what if she had? Would that have made things better for Justin? Or worse? Many children prefer that their personal humiliations not be brought to the attention of their parents, and given that Justin did not tell his parents himself, he may well have fallen into that category on this occasion at least. Sometimes in the exercise of good judgment, school counselors must overrule the wishes of their charges on such matters. But sometimes good judgment

requires that the child's wishes be respected. In what respect does oversight from the Department of Education increase the likelihood that the right decision will be made?

The other incident Ms. Aaberg reported was indeed communicated to her by her son. She testified that two months prior to his death he confided that a "kid" had once told him that because he was gay he was going to hell. Ms. Aaberg did not testify whether she knew where or when this conversation involving her son and the other young person occurred, the tone of voice with which the student spoke, whether the teachers, counselors or principal knew about it or had reason to know about it. She simply gave her opinion that the First Amendment should not cover such speech. Tr. at 296.

Despite knowing of this incident, Ms. Aaberg testified before the Commission that up until his suicide "he always looked so happy and I honestly thought he had the perfect life." He had many friends, and according to her testimony, he evidently did not wish to bother them with his problems any more than he wanted to bother his family. Statement of Tammy Aaberg at 1. No one realized that he was about to take his own life. All of this is perfectly understandable and my sympathy goes out to Ms. Aaberg and her son's family and friends. But it may well be that he looked happy to his teachers and counselor too. They may also have mistakenly thought he had the perfect life.

Life teaches us that human beings are not always what they appear to be on the surface. But no one has ever suggested that the problems of navigating the human soul can be made easier with more aggressive federal oversight.

³⁷ It is worth noting that a significant by-product of the Department of Education's Dear Colleague Letter of October 26, 2010 is to increase the demand for anti-bullying seminars and education programs—and not just by a little bit. In the Letter, Assistant Secretary Russlynn Ali makes it clear that "school administrators should look beyond simply disciplining the perpetrators [i.e. bullies]." "While disciplining the perpetrators is likely a necessary step, it often is insufficient." Instead, she repeatedly urges "training faculty on constructive responses to racial conflict," "[p]roviding faculty with training to recognize and address anti-Semitic incidents," and "creat[ing] an age-appropriate program to educate its students about the history and dangers of anti-Semitism." In response to one hypothetical featuring sexual name-calling and rumor mongering, Assistant Secretary Ali states "The school should have trained its employees on the type of misconduct that constitutes sexual harassment." She again makes it clear the "responding to individual incidents of misconduct on an ad hoc basis only" is insufficient." In connection with a hypothetical involving the bullying of a disabled student, she states that the proper response should "at least" have included (among other things) "special training for staff on recognizing and effectively responding to harassment of students with disabilities."

By the end of the 10-page letter, only a fool would have failed to note that the best way to avoid liability—perhaps the only way—is to engage lots of trainers.

Training is obviously not always a bad thing. But when schools undertake such training in response to what they perceive to be a government mandate, they are overwhelmingly likely to just go through the motions.

Approximately twenty years ago, see n.18, *supra*, employers seeking to avoid Title VII sexual harassment lawsuits for monetary damages began to hire outside consultants to train their employees on proper workplace decorum. In doing so, some hoped their employees would learn to avoid conduct that could be construed as sexual harassment. More important, however, they hoped these training courses would provide them with some immunity against punitive damages. Consequently, it didn't matter whether an employer thought its employees needed sexual harassment training or not; they were going to get it.

In California, where I live, the businesses providing these training courses became powerful enough to secure a state law requiring all supervisory employees at all workplaces, both public and private, to take such a course every other year. See Cal. Gov. Code § 12950.1 (2011).

It seems overwhelmingly likely that the advocacy groups and private businesses that provide bullying training have received a special stimulus from the Department of Education's Dear Colleague Letter. A representative of one of them, the Gay, Lesbian and Straight Education Network ("GLSEN"), testified at our briefing in favor of the Department of Education's policy.

³⁸ See, e.g., Richard Florida, *The Rise of the Creative Class: Why Cities Without Gays and Rock Bands are Losing the Economic Development Race*, *Washington Monthly* (May 2002).

One expert, Cornell University professor of human development Ritch Savin-Williams, has expressed concern that current scholarship on gay, lesbian and bisexual youth tends to be "doom-and-gloom" and that scholarship "[a]ccentuating the assets, resiliency, and complexity of same-sex oriented youth as creative, artistic, versatile, assertive, stylish, witty, sensitive, and athletic does not exist." Ritch C. Savin-Williams, *Then and Now: Recruitment, Definition, Diversity, and Positive Attributes of Same-Sex Populations*, 44 *Developmental*

Psychology 135, 137 (2008). Alas, the political system tends to reward those who can claim to be disadvantaged, particularly if they can claim to have been victimized.

Savin-Williams also points out what he calls a "perplexing contradiction" in the social science literature on sexual minorities:

Although gay youth are purported to be severely disturbed, once adulthood is reached, they somehow become good partners and parents. How can it be that young lesbians, who reportedly have high levels of nearly every risk behavior imaginable, grow up to be such good partners and parents? One pessimistic perspective is that disturbed lesbian youth are eliminated through their pathology, with suicide being the most obvious. Alternatively, as they age, broader and more representative subgroups of same-sex attracted women come out, establish relationships, and identify some aspect of their same-sex sexuality on research surveys. Another explanation is political in nature. Highlighting 'bad' gay youth and 'good' gay adults garners resources: community support services and school-based gay/straight alliances for youth and legal rights in legal same-sex parenting and marriage court cases for adults.

Id. at 137. See also Ritch C. Savin-Williams, *The New Gay Teenager* (2005)(arguing that the image of sexual minority teenagers as depressed and suicidal may be exaggerated).

³⁹ It is the practice of the Commission for Commissioners to share their Statements and to then allow 30 days for Commissioners to add rebuttal material to their Statements or to draft a separate Rebuttal Statement. My citations are to the draft Statements, which did not contain rebuttal material at the time I had access to them.

⁴⁰ This is a random sampling of the articles, and not an effort to find the most troubling case in each category. There has been insufficient time for anything else.

⁴¹ Commissioner Roberta Achtenberg at 103 (quoting Report at 14-15)(citation were omitted in the Achtenberg version).

⁴² Liza Little, Middle Class Mothers' Perceptions of Peer and Sibling Victimization among Children with Asperger's Syndrome and Nonverbal Learning Disorders, 25 *Issues of Comprehensive Pediatr. Nurs.* 43 (2002)

⁴³ Susan Carter, Bullying of Students with Asperger Syndrome, 32 *Issues Comprehensive Pediatric Nursing* 145, 146, 150 table 2 (2009).

⁴⁴ Little at 47-48.

⁴⁵ Carter at 148.

⁴⁶ Carter at 150 (only 18 respondents, those with children ages 4-14 were asked the questions on social shunning).

⁴⁷ Fred R. Volkmar & Ami Klin, Diagnostic Issues in Asperger Syndrome, in *Asperger Syndrome* 25, 31, 35 (Ami Klin, Fred R. Volkmar & Sara S. Sparrow eds., 2000).

⁴⁸ It should be noted that these very useful studies were not written for the purpose of justifying a federal bullying policy. Rather they were intended to provide information to pediatric nurses and other health professionals that would take them a step beyond their own clinical observations. In the absence of this evidence, these professionals would have even less to go on.

⁴⁹ On the other hand, this can be carried too far. Sometimes advocacy organizations are in the best position to bring problems to public attention that might otherwise be neglected.

⁵⁰ The Sikh Coalition, *Hatred in the Hallways: A Preliminary Report on Bias Against Sikh Students in New York City's Public Schools* (June 2007).

⁵¹ This is clear because the summary of the results repeatedly refers to students who wear "*patkas*," which are head coverings worn by young boys before they are old enough to wear turbans. A Sikh Coalition video also features a photograph of a quite young boy being interviewed for the survey. See Sikh Coalition, *Sikh Coalition NYC Civil Rights Survey* (May 11, 2007), available at <http://www.youtube.com/watch?v=j61q1LTaN-8>.

⁵² It is worth pointing out that the high rates of teasing and/or harassing on account of religion for Sikh children seems to be confined to boys—likely for the obvious reason that they are ones who wear turbans or *patkas*. The study stated that "77.5% of Sikh boys we surveyed who go to school in the borough of Queens report being teased or harassed on account of their Sikh identity." In contrast, "58.4 percent of Sikh students report being teased or harassed at school on account of their Sikh identity. For reasons that are not discussed in its report, the Sikh Coalition interviewed approximately twice as many boys as girls (65.4% vs. 34.6%) in its study. Given the turban/*patka* issue, this, of course, artificially inflates the numbers of children who have been teased and/or harassed.

⁵³ If it is any consolation, I grew up during the Cold War, and I was accused by another child of being a spy for what was then commonly called "Red China." Just as Sikhs are not Muslim, I am not Asian. I do have dark, straight hair, or at least I did. And even if I were Asian, I am not a spy. The little girl who accused me of this later became a close friend. I am not trying to make light of all accusations suffered by Sikhs. Some are obviously more serious than others. For example, in the days directly after September 11, 2001, Frank Silva Roque, a man with

serious mental problems, killed Balbir Singh Sodhi, a Sikh gas station owner in Arizona, believing him to be a Muslim terrorist. Roque was convicted and sentenced to death, but the Arizona Supreme Court reduced his sentence to life imprisonment, citing as mitigating factors both his low IQ and mental illness. But just as not all accusations that a Sikh is a terrorist are insignificant child's play, some really are insignificant child's play. *Hatred in the Hallways* fails to make distinctions among accusations and hence is not particularly helpful.

⁵⁴ These statements were made before the project was completed. She also stated in the video, "Our goal is to have 1000 surveys completed by the end of the project, and our larger goal is to take these numbers and present them to government agencies who can help our community in different ways...."

⁵⁵ Sikh Coalition NYC Civil Rights Survey (May 11, 2007), available at <http://www.youtube.com/watch?v=j61q1LTaTn-8>.

⁵⁶ I note that unlike in most scholarly articles (and I surely do not wish to imply here that scholarly studies are not also subject to political bias), in *Hatred in the Hallways*, the reader is not told how the questions to the survey subjects were worded.

⁵⁷ AAUW Educational Foundation, *Hostile Hallways: Bullying, Teasing and Sexual Harassment in School* (2001).

⁵⁸ *Id.* at 12, Figures 3 & 4.

⁵⁹ *Id.* at 29.

⁶⁰ *Id.* at 27.

⁶¹ The question propounded to students was, "During the past 12 months, how many times on school property were you harassed or bullied for any of the following reasons?" Among the reasons listed was "Race, Ethnicity or National Origin." Anyone who answered more than never would have been included in the tally.

⁶² Tonja R. Nansel, Mary Overpeck, Ramani S. Pilla, W. June Ruan, Bruce Simons-Morton & Peter Scheidt, *Bully Behaviors Among US Youth: Prevalence and Association with Psychosocial Adjustment*, 285 JAMA 2094 (April 25, 2001).

⁶³ The difference between white and Hispanic was not statistically significant. *Id.* at 2097, Table 2. Similarly, 8.8% of white students, 6.7% of black students and 8.1% of Hispanic students reported that they were bullied on a weekly basis. These differences, however, were not statistically significant.

⁶⁴ Statement of Commissioner Achtenberg at 101 (quoting Report at 12).

⁶⁵ Nansel at 2097. The rates among students who reported that they had ever been bullied were as follows: "Belittled about religion or race" (25.8%), "Belittled about looks or speech" (61.6%), "Hit, slapped, or pushed" (55.9%), "Subjects of rumors" (55.6%), Subjects of sexual comments or gestures" (52.0%).

⁶⁶ *Id.* at 2097

⁶⁷ The "It Gets Better" Project was founded by Dan Savage and Terry Miller in response to suicides of gay teenagers. Its purpose is to urge them to hang in there; life as an adult will be better. This message strikes me as important for all pre-teens and teenagers, straight or gay, bullied or non-bullied. Few teenagers find growing up easy. Adults who tell adolescents that "These are the best years of your life" are frequently well meaning, but their words are not very comforting and (mercifully) usually inaccurate.

⁶⁸ Statement of Commissioner Achtenberg at 109, quoting Emily O'Mally Olsen, Tim McManus, Steve Kinchen, David Chyen, William A. Harris, Howell Wechsler, *Sexual Identity, Sex of Sexual Contacts, and Health-Risk Behaviors Among Students in Grades 9-12—Youth Risk Behavior Surveillance, Selected Sites, United States, 2001-2009*, Centers for Disease Control and Prevention, Morbidity and Mortality Weekly Report (June 6, 2011)(Early Release).

⁶⁹ These figures are medians of the results of 13 state-wide and local surveys. The figures for reported attempted suicides broken down by actual sexual contacts (rather than reported sexual orientation) were 8.4% (opposite sex sexual contacts only), 19.7% (same sex sexual contacts only) and 29.8% (sexual contact with both sexes). Students were asked about their conduct for the 12 month period immediately preceding the point during which they filled out the questionnaire.

⁷⁰ Olsen et al, at 75, Table 26. Again, these figures are medians of 13 state and local studies. The figures are for any 30-day period, and do not necessarily imply that a student was currently smoking daily.

⁷¹ *Id.* at 89, Table 40.

⁷² *Id.* at 90-102, Tables 41-53. For example, 4.6% of heterosexual, 22.9% of gay or lesbian and 20.4% of bisexual students report using the drug ecstasy. *Id.* at 97, Table 48.

In view of this, it does not seem surprising to me that sexual minority students are more likely to "receive punishment from schools, police or courts." See Statement of Commissioner Roberta Achtenberg at 111 (quoting Institute of Medicine of the National Academies, *The Health of Lesbian, Gay, Bisexual, and Transgender People: Building a Foundation for Better Understanding* 159 (2011). Commissioner Achtenberg cites the Institute of Medicine report for the proposition that this disproportionate discipline was somehow unmerited. In fact,

however, the reference she cites is merely a citation to another article. It is not an endorsement of that other article's findings. See Kathryn E.W. Himmelstein and Hannah Brickner, *Criminal-Justice and School Sanctions Against Non-Heterosexual Youth: A National Longitudinal Study*, 127 *Pediatrics* 49 (January 2011). Two days after the internet version of the article was published, a letter dated December 8, 2010 from Donald J. Harris, Ph.D. sent to *Pediatrics* stated: "There is a sharp disconnect between the statistical findings presented in this report and the authors' conclusion that 'nonheterosexual youth suffer disproportionate educational and criminal-justice punishments that are not explained by greater engagement in illegal or transgressive behaviors.' ... [T]he categorical language of the authors' conclusion is based almost entirely on a pattern of findings that did not reach the stated criterion of statistical significance." See *Replies to Criminal-Justice and School Sanctions Against Nonheterosexual Youth: A National Longitudinal Study*, *Pediatrics* web site. If this Report were not put together so hurriedly, perhaps we would have had time to figure out who is right.

⁷³ *Id.* at 115, Table 66. There is, however, research that finds that eating disorders are more common among gay, lesbian and bisexual students than they are among heterosexual students. S. Austin, N.J. Ziyadeh, H.L.

Corliss, M. Rosario, D. Wypi, J. Haines, C.A. Carmago, Jr. & A.E. Field, *Sexual Orientation Disparities in Purging and Binge Eating from Early to Late Adolescence*, 45 *J. Adolescent Health* 238 (2009).

⁷⁴ There may indeed be external structural issues that are contributing factors to the high rates of high-risk behavior on the part of gay, lesbian and bisexual youth. But they do not all relate to victimization. For example, since sexual minorities are minorities, the search for love may be a little harder. They are less likely to find a soul mate or even a reasonably compatible mate within a short distance from their home. As a result, they may be less likely to form satisfactory romantic relationships while still in school. A failed relationship may be a greater problem, since the common adage that there are "plenty of fish in the sea" may not apply. Another external structural issue relates to family structure. Through genetic inheritance, white parents tend to give birth to white children, while Asian parents tend to give birth to Asian children. Through cultural inheritance, Roman Catholic parents tend to have Roman Catholic children and Buddhist parents have Buddhist children. But most gay, lesbian or bisexual children are being reared by their own biological, heterosexual parents or parent. (Gay, lesbian and bisexual adults sometimes have biological or adopted children, but those children are usually heterosexual, thus creating the problem in reverse.) No doubt the pressures of parental disapproval can be a problem for sexual minority children. But even in the absence of disapproval, anything that makes a child different from his or her parents places some element of stress on the relationship. Sexual orientation is just one more such potential difference. Sympathetic parents, for example, may wish to provide advice on romantic relationships, but feel inadequate to the task, since their experience is dissimilar. Or their children may perceive them to be inadequate to the task, when in fact they are quite able to help, but their advice is not sought.

⁷⁵ She later states her point more modestly (and much more defensibly): "The reasons that sexual minority youth may experience suicidal ideation and/or acts in response to victimization are not entirely clear. Nevertheless, social stigma may well drive some number of these experiences." Statement of Commissioner Roberta Achtenberg at 111-12.

⁷⁶ See Ritch C. Savin-Williams, *Then and Now: Recruitment, Definition, Diversity, and Positive Attributes of Same Sex Populations*, 44 *Developmental Psych.* 135 (2008) (internal citations omitted). In that article, Dr. Savin-Williams writes intriguingly about the issue: "[M]ost researchers assume that it is not same-sex sexuality per se that impacts development but the victimization, discrimination, and stigmatization that it engenders. If so, what is it about sexual prejudice that is developmentally more deleterious to the recipients than other forms of social ostracism to their recipients, such as that meted out to women, ethnic minorities, the poor, the unattractive, the overweight, or the disabled? Alternatively, one might argue (but few do) that because of their possibly altered hormonal and anatomical constitution, same-sex attracted individuals navigate a unique developmental instability or fluctuation across a range of personal attributes (sex object choice, cognitive skills, physical features, hobbies, career choices). The sex atypicality of same-sex populations suggests that some same-sex attracted individuals have a different brain structure, physiology, or hormonal status than others of their biological sex. Whether these potential biological differences make same-sex oriented individuals unique, and if so, to what degree are unknown, largely because the biologic data are so preliminary that few direct or indirect pathways have been established."

⁷⁷ Asian/Pacific Islander females had the third highest rate of suicide among females, followed by Hispanics and non-Hispanic blacks. Among males, non-Hispanic blacks had the third highest rate, with Hispanic males at a very close fourth and Asian/Pacific Islander males with the fifth-highest rate. Rates were age-adjusted. See Centers for Disease Control and Prevention, *National Suicide Statistics at a Glance* (2002-2006).

- ⁸⁰ *Id.* at 346. For example, 19.7% of those classed as having "low rejection scores" reported suicide attempts, while 35.1% of those with moderate rejection scores and 67.6% of those with high rejection scores did. Similarly, 22.4% of those with low rejection scores, 44.6% of those with moderate rejection scores, and 63.5% of those with high rejection scores reported depression. *Id.* at 350, Table 4.
- ⁸¹ The data on the relationship of family rejection with heavy drinking and with sexually transmissible disease diagnosis were not statistically significant. *Id.* at 350, Table 4.

End Notes for Statement of Commisioner Michael Yaki

- ¹ In a report released last year – prior to the changes in membership on the Commission that approved this Report -- my Statement on the Multiethnic Placement Act report focused on the failure of the Commission to address same-sex adoption: "However, the Commission majority, by its actions to date, has consistently refused to act in accordance with our mandate to ensure justice and equal treatment for all Americans. By that I am explicitly discussing the need for this Commission to recognize continued discrimination against Americans who are gay, lesbian, bisexual or transgender. This void in our mandate is evident by this report's refusal/inability to explore or to encourage facilitation of adoption by one important sector of the American population: gay men and lesbians."
- ² Indeed, given that state action is involved in educating (and protecting) K-12 children, and that this is limited to a distinct group, any law should pass muster under the "congruent and proportional" test of *City of Boerne v. Flores*, 521 U.S. 507 (1997).

ABSTRACT

Bullying victimization is a serious problem among in-school adolescents. Because of limited reports on bullying among adolescents in Benin, a study was conducted to determine the prevalence and correlates for bullying victimization among school-going adolescents in Benin. Secondary analysis of data was conducted using the 2009 Benin Global School-based Health Survey (GSHS) data. Logistic regression analyses were done to estimate associations between the outcome (bullying victimization) and selected explanatory variables. Out of 2,690 in-school adolescents, 49.3% were of age 16 years or older, 66.9% were males and 40.1% reported having been bullied at least once in the previous 30 days to the survey (39.2% among boys versus 42.0% among girls). Male

* Corresponding Author's Email: mazmazli@yahoo.com.

adolescents were 11% (adjusted odds ratio (AOR) = 0.89; 95% confidence interval (CI) 0.88–0.90) less likely to be bullied compared to female adolescents. Participants who drank alcohol were 45% more likely to be bullied than those who did not drink alcohol (AOR = 1.45; 95% CI 1.43–1.47). Adolescents who smoked cigarettes were 24% (AOR = 1.24; 95% CI 1.21–1.28) more likely to be bullied compared to non-smokers. Those who reported being involved in physical fighting were 77% more likely to be bullied than those who were not involved in physical fighting (AOR=1.77; 95% CI 1.75–1.79). Adolescents who had parental supervision were 10% (AOR = 0.90; 95% CI 0.89, 0.91) less likely to be bullied than those who did not have parental supervision. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

INTRODUCTION

Bullying victimization is a serious problem among in-school adolescents and has a long term effect on problem behaviour in young adulthood (1). Bullying is associated with truancy from school (2) and affects school achievement (3). It has also been associated with health problems (4–7) such as depression and suicidality.

Bullying victimization is a common problem among children and adolescents across the globe. Its prevalence varies across countries partly due to differences in the definition, study design and sample (8). Among 28 European countries, the prevalence of being bullied in previous last year varied from 6% in Sweden to 40% in Lithuania (9). Meanwhile, in 19 low- and middle income countries, the prevalence of being bullied in the previous 30 days ranged from 7.8% in Tajikistan to 60.9% in Zambia (10). In the United States, about 10% of school going children were bullied (11), and in Canada an average of 16% of the children (17.8% of boys and 15.1% of girls (12)) were frequently victimized (13). In Asia, prevalence of being bullied was 27.8% in Thailand (14), 19.0% in Guangdong province in China (15), 8% in Western Turkey (16), 35.5% were bullied in Philippines (17), and 14% of the students were bullied in Korea (18). In a study involving 40 countries, Craig et al. (19) observed that adolescents in Baltic countries reported higher rates of being bullied, whereas northern European countries reported the lowest prevalence.

Demographic factors have been associated with bullying victimization. In middle-income countries, male gender (10, 20, 21) and younger age (10, 22) have been associated with bullying victimization. Substance use has also been reported to be associated with bullying victimization (23). Tharp-Taylor et al. (24) have reported an association between cigarette smoking and bullying victimization and between marijuana use and bullying victimization. Bullying victimization has also been associated with physical fighting (20, 22, 25). Factors associated with bullying victimization have not been consistent across countries partly due to differences in the selected variables for analysis. Hence, it is important that each population establishes risk factors for bullying victimization for use in designing interventions to curtail or prevent bullying.

This study involved further analysis of data from the Benin Global School-based Health Survey (GSHS) that was conducted in 2009. The survey was developed by the World Health Organization (WHO) in collaboration with the United Nations Children's Fund (UNICEF), United Nations Educational, Scientific and Cultural Organization (UNESCO), and Joint United Nations Program on HIV/AIDS (UNAIDS) with technical assistance from the Centres for Diseases Control and Prevention (CDC), Atlanta, Georgia, United States.

The GSHS aims to provide data on health and social behaviours among in-school adolescents. Further details of the GSHS have been reported elsewhere (26). Among the 13-15 years old pupils in Benin, 42.1% (42.7% of boys and 40.7% of girls) were bullied (27). Because this analysis was limited to the 13-15 years age group and no attempt was made to determine factors associated with bullying in Benin, we conducted further analysis of the 2009 Benin GSHS to determine the prevalence of bullying and its correlates in the school-going adolescents in Benin.

OUR STUDY

The Republic of Benin with a population of 9.98 million is located in West Africa, bordering with Togo in the west, Nigeria in the east and Burkina Faso and Niger in the north. The capital city of Benin is Porto-Novo. Literacy (ability to read and write) among persons aged 15 years or older was 55.2% of males and 30.3% of females. The population comprised of 42.8% Christians, 24.4% Moslems, 17.3% practices Vodun and 6.5% claimed no religion affiliation (2013 census). During pre-colonial era, young boys were often apprenticed to older soldiers, and Benin was characterized by ethnic strife during post-colonial era with six coups between 1963 and 1970 (<http://en.wikipedia.org/wiki/Benin>. Accessed 2014 January 15).

A School-based Health Survey was conducted in 2009 among students in grades 10 to 12 in Benin. A total of 2690 students participated in the survey. The response rate and sampling methods that were used in the survey are described in greater detail elsewhere (27). The school response rate was 100%, the student response rate was 90%, and the overall response rate was 90%. A two-stage cluster sampling technique was used to draw the sample. At the first stage of sampling, schools were randomly selected with probability proportional to enrollment size. At the second stage of sampling, classes were randomly selected and all students in selected classes were eligible to participate.

The data set and code book were made available to the public on the GSHS website (<http://www.cdc.gov/gshs/>. Accessed 2014 February 15). The privacy of students was protected by allowing for anonymous and voluntary participation. No school identifier was included in the data that was deposited in the public domain.

The survey obtained information among other subjects on bullying; alcohol use; tobacco use; parental supervision and violence. The questionnaire was self-administered by students. Bullying victimization was the outcome variable. It was explained as follows: "Bullying occurs when a student or group of students say or do bad and unpleasant things to another student. It is also bullying when a student is teased a lot in an unpleasant way or when a student is left out of things on purpose. It is not bullying when two students of about the same strength or power argue or fight or when teasing is done in a friendly and fun way." Students were then asked the following question: "During the past 30 days, on how many days were you bullied?" The responses were: 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. Those reporting one or more days were considered to have been bullied. The independent variables were identified from the literature as associated with bullying.

The following were the exposure variables that were considered in the analysis:

- Alcohol consumption: the variable was obtained by asking the question “During the past 30 days, on how many days did you have at least one drink containing alcohol?” The responses were: 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. The variable was categorized as having drunk alcohol in the previous 30 days to the survey, if pupil drank 1 or more drinks containing alcohol; otherwise they were categorized having not consumed alcohol in the same period.
- Smoking cigarettes: Pupils were asked “During the past 30 days, on how many days did you smoke cigarettes?”; and the responses were 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. Smoking cigarettes was categorized into having smoked cigarettes in the previous 30 days to the survey if the pupil smoked cigarettes on 1 or more days in the previous 30 days to the survey; otherwise the pupil did not smoke cigarettes.
- Parental supervision: pupils were asked the question “During the past 30 days, how often did your parents or guardians really know what you were doing with your free time?” The responses were never, rarely, sometimes, most of the time and always. The responses were categorized into having not received parental supervision if they were never supervised; otherwise they received parental supervision.
- Physical fighting: a physical fight was explained as: “A physical fight occurs when two students of about the same strength or power choose to fight each other”. The pupils were asked the following question: “During the past 12 months, how many times were you in a physical fight?” The responses were 0 times, 1 time, 2 or 3 times, 4 or 5 times, 6 or 7 times, 8 or 9 times, 10 or 11 times and 12 or more times. Pupils who were involved in 1 or more times of physical fight were labeled as being involved in a physical fight during the previous 12 months to the survey; otherwise they were deemed as not having been involved in a physical fight in the same period.

Weighted prevalence of the main outcome (bullying victimization) and socio-demographic characteristics were calculated. Bivariate and multivariate logistic regression analyses were done to determine associations between bullying victimization and relevant variables according to the literature. A weighting factor was used in the analysis to reflect the likelihood of sampling each student and to reduce bias by compensating for differing patterns of non-response. The weight used for estimation is given by the following formula:

$$W = W1 * W2 * f1 * f2 * f3 * f4$$

where

W1 = the inverse of the probability of selecting the school,

W2 = the inverse of the probability of selecting the classroom within the school,

f1 = a school-level non-response adjustment factor calculated by school size category (small, medium, large),

f2 = a class-level non-response adjustment factor calculated for each school,

f3 = a student-level non-response adjustment factor calculated by class, and

f4 = a post stratification adjustment factor calculated by grade.

We report unadjusted odds ratios and their 95% confidence intervals from univariate logistic regression analyses for selected predictor variables while considering having been

bullied in the past month as a dependent variable. We also report results from a multivariate logistic regression analysis (adjusted odds ratios and their 95% confidence intervals) to determine independent predictors for the outcome.

FINDINGS

A total of 2,690 in-school adolescents participated in the Benin Global School-Based Survey of 2009. For those study participants whose data were available, 49.3% were of age 16 years or older, 66.9% were males and 40.1% reported having been bullied in the past month (39.2% among boys versus 42.0% among girls). Further description of the study sample is given in Table 1.

%* - weighted percent; n** - unweighted frequency.

Factors associated with being a victim of bullying

Bivariate and multivariate analyses produced similar results (see Tables 2 and 3). In Multivariate analysis, male adolescents were 11% (adjusted odds ratio (AOR) = 0.89; 95% confidence interval (CI) 0.88–0.90) less likely to be bullied compared to female adolescents.

DISCUSSION

In this most recent 2009 Global School Health Survey conducted in Benin, 40.1% of the students (39.2% among boys versus 42.0% among girls) reported having been bullied in the previous 30 days to the survey. Subpopulations at increased risk for being bullied were adolescents aged 15 years, female gender, alcohol drinkers, smokers and adolescents who were involved in physical fighting. Meanwhile, parental supervision was protective to being bullied. The prevalence in the current study is alarmingly high, although the lowest as compared to other West African countries.

A total of five countries (Benin, Algeria, Mauritania, Ghana and Senegal) have been participating in the Global School Health Surveys in West Africa (28). Among the 13-15 years-olds, the prevalence of being bullied was the lowest in Benin with an overall prevalence of 42.1% (42.7% among boys and 40.7% among girls) compared to overall prevalence rates of the other West African countries ranging from 47.2% to 58.7% (boys 48.0% to 60.7%; and girls 46.3% to 57.3%). The overall prevalence of 40.1% in the current study which included individuals younger than 13 years and older than 15 years is lower than the 52.3% observed in

Uganda (29), 51.3% (54.2% males and 52.2% females) reported in Botswana (30) and 62.8% (60.0% of male and 65.0% of female) reported in Zambia (31). Generally, prevalence estimates for bullying victimization have varied within and between countries, within and between regions, and within and between continents. These variations may reflect cultural differences in the definitions of bullying (32) and bullying victimization (19).

Associations between bullying victimization and gender have not been consistent. Craig et al. (19) observed that rates of victimization were higher for girls than boys in 29 out of 40 that they studied. In the current study girls were more likely to be bullied than boys, contradicting a finding reported in Zambia by Siziya et al. (31). Knowledge on the type of bullying may help in clarifying the sex difference in bullying victimization. If verbal, sexual and relational bullying are the dominant types of bullying in a population, more girls than boys may be bullied. Vieno et al. (33) reported that girls were more likely to be victims of verbal, relational and sexual bullying than boys, with the boys being bullies in these forms of bullying.

It was observed in the current study that adolescents aged 15 years were more likely to be bullied than older students. This finding is not consistent with the observations of Craig et al. (19) that bullying victimization decreased with age among boys in 30 of the 40 countries, and in 25 out of 39 countries among girls. Craig et al. (19) propose that the reduction in victimization by age may partly be due to age related changes in youth adapting socially as they develop or reflect equalization in physical sizes and consequently, increased effectiveness at inhibiting bullying, and partly it may be due to adolescents who bully may be targeting a fewer number of students with increasing age or targeting younger children. It is not clear why there was no difference in the prevalence of being bullied between adolescents aged less than 15 years and adolescents aged 16 years or older.

Drug abuse facilitates risky situations where bullying can occur. The finding in the current study that alcohol is associated with bullying victimization concurs with findings elsewhere (2, 31, 34, 35). Students who drank alcohol might have found themselves in situations that when drunk they might have been involved in some type of bullying such as physical fighting. Bullying victimization has also been associated with smoking cigarettes (34) and dagga (2, 36). The significant, positive association between victimization and substance use underscores the need to intervene with bullying behaviors among adolescents (37).

The finding that students who received parental supervision were less likely to be bullied in the current study is consistent with the observation made in Beijing by Hazemba et al. (34). This finding is also consistent with the observation by Jeong and Lee (38) who indicated that adolescents with parental support were less likely to be victims of school bullying, and lack of involvement and support from parents is likely to increase the risk of bullying victimization (39). While lack of parental supervision has been associated with smoking (40) and less cohesive family behaviour associated with alcohol use in cross sectional studies, cohort studies are needed to establish the protective effect of the parental supervision. Parents who are not involved in fighting are good role models for their children who may not find themselves in situations where bullying may occur. Furthermore, being under the watchful eye of the parents, adolescents may keep out of trouble.

Students who were involved in physical fighting were more likely to be bullied in the current study than adolescents who were not involved in physical fighting. In another study, a dose response has been observed between bullying victimization and physical fighting (41), thus providing more evidence that physical fighting may be an exposure to bullying.

Adolescents involved in fighting might have been bullied by older adolescents in retaliation for their involvement in fighting.

Factors associated with bullying victimization have varied between studies partly because of the differences in the factors that were selected for the studies. Hence it is important that risk factors are determined for the population to be targeted for intervention to curtail or prevent bullying victimization.

Because of the cross sectional study design, we are unable to provide adequate evidence that observed factors are predictive risk factors for bullying victimization. For instance, in the association between alcohol consumption and bullying, adolescents might have consumed alcohol as a result of being bullied. Comparisons of the prevalence in the current study with those obtained in other studies may be biased as a result of differences in defining the term bullying victimization. However, comparisons with results from other Global School Health Surveys are valid as they use the same definition. The major strength of the current study was the large sample size. Responses may have been biased towards socially accepted norms. We cannot rule out recall bias as participants were at times required to recall events that may have happened over a long time ago (1-12 months ago).

In-school adolescents in Benin report a lower prevalence of bullying victimization than other countries in West Africa. Parental supervision and being a male were associated with lower likelihood of bullying victimization; Smoking, alcohol drinking, and physical fighting were associated with a history of bullying victimization. Interventions aimed at promoting adolescents health would benefit from taking these observations into consideration. The information contained in the current study would also form as a baseline data for use in such interventions to curtail or prevent bullying among adolescents in schools.

ACKNOWLEDGMENT

The authors thank the World Health Organization (WHO) for developing the global school health survey in collaboration with United Nations' UNICEF, UNESCO, and UNAIDS; and with technical assistance from CDC (<http://www.cdc.gov/gshs/>. Accessed 24 December 2013). The authors also thank the survey officers and students who took part in the survey.

Chapter 112

**MOTHER BLAME: THE RESILIENCE AND
DECISION-MAKING ABILITIES OF MOTHERS
WITH A SCHOOL-AGED CHILD WHO HAS BEEN
ACCUSED OF BULLYING**

***Erin Jarvis*, Psych Hons

Edith Cowan University, Joondalup, Western Australia, Australia

ABSTRACT

It is estimated that 20% of children frequently bully. Although the research on victims of bullying in childhood is extensive, considerably less research has been conducted on bullies themselves or the parents of bullies. Hence, this chapter addresses this knowledge gap by examining the resilience and decision-making outcomes of mothers with a child accused of bullying by comparing the results with mothers who do not have a child accused of bullying. A total of 157 mothers, 34 mothers of accused bullies, 123 mothers of children not accused of bullying, completed a questionnaire. The questionnaire comprised of four individual surveys, namely, the Individual Resilience Scale, Brief COPE, Multi-dimensional Scale of Perceived Social Support (MSPSS) and the Decision Outcome Inventory (DOI), which were administered using the online software program Qualtrics. Independent sample *t* tests were used to analyse the data. The results revealed that the resilience of mothers of accused bullies was lower than mothers of children not accused of bullying. In addition, humour and perceived social support from friends was also less in mothers of accused bullies than mothers of non-bullying children. There was no significant difference in decision-making outcomes between mothers of bullies and non-bullies. It is intended that these results will increase the awareness of the behaviours of mothers of accused bullies and inform the construction of intervention programs to assist such mothers.

INTRODUCTION

As a subcategory of antisocial behaviour, the act of bullying is unacceptable by societal norms as it causes unjustifiable harm to others (Baumeister & Lobbestael, 2011). Olweus (1994) defined bullying as the repeated behaviour of an individual involving a physical or psychological imbalance of power to ensure social dominance. Rigby and Smith (2011) expanded on this definition by stating that the bully must have the intent to dominate and a desire to humiliate the victim. Therefore, in the school setting, bullying goes beyond the playground teasing and taunting that occurs between children who are physically and socially equal, to the unequal victimisation and abuse by one child over another (Buxton, Potter, & Bostic, 2013). Whilst it is unclear whether children are able to differentiate between the act of bullying and peer harassment (Baly & Cornell, 2011), it is common for the term bully to be misinterpreted, for often the focus is placed on the child's aggression rather than on the repetitive and intentional nature of their actions (Vaillancourt et al., 2008). Thus, it is important to note that bullying is not always physically violent in execution (i.e., hitting, pushing). It can also be verbal (i.e., name calling, taunting), relational (i.e., social exclusion) or cyber (i.e., online), (Wang, Iannotti, & Nansel, 2009). Bullying, likewise, can be direct or indirect (Farrington & Baldry, 2010) and gendered. Boys tend to use direct bullying which typically involves confronting the victim face-to-face in a belligerent manner whilst using express threats of violence with the intention of causing physical injury or harm to the victim (Farrington & Baldry, 2010). In contrast, girls are inclined to use indirect bullying, particularly cyber bullying, as this allows them to avoid physical conflict, yet inflict sufficient harm to ensure the social isolation of their victim (Farrington & Baldry, 2010).

The first longitudinal study to investigate these various interpretations of bullying behaviour found that the origin and judgment of such behaviour were of significance (Lee, Smith, & Monks, 2011). In this regard, Lee, Smith and Monks (2011) asked 113 South Korean participants questions on their perception of bullying and why they thought bullying occurred. Their results revealed age-related differences in so far as mothers, and children aged 15-17 years, both considered bullying to be unacceptable, however, younger children aged 10-15 years were more accepting of bullying. These findings are at odds with an earlier study, which found parents of primary school children aged 6-11 years believed that a small amount of bullying was acceptable, as in their estimation it helped to build character (Eslea & Smith, 2000). Solomon, Bradshaw, Wright and Cheng (2008) suggest that parental views of bullying (especially in relation to aggressive behaviour) may affect how a child behaves in school.

Parents of accused bullies have also been found to be less likely to identify their child's bullying behaviour as being antisocial, but rather to view their child's bullying as a normal part of childhood (Alphonse, 2010). Huddleston, Varjas, Meyers and Cadenhead (2011) identified perceptual differences between teachers' and mothers' interpretation of bullying events. For in a case study of one bullying event, both the school administration and the child's teachers described an accused bully as being a child who verbally abused and annoyed other students to the point where they became physically aggressive towards the bully. The mother of the accused child, however, claimed that her child was simply reacting to the other students' verbal aggression and, therefore, viewed her child to be the victim, and not the bully.

What has also been reported is that parents who express tolerance of their child's bullying behaviours typically concede that they are unable to control their child's actions (Nation, Vieno,

Perkins, & Santinello, 2008). Other research has determined that children who bully tend to victimize children of their own age and in the same class more often than they do older children (Boulton & Underwood, 1992).

Cross and colleagues (2006) recent statistical findings on the prevalence of bullying behaviour in Australia revealed that of the 8,000 school children aged 12-14 years they surveyed 20% admitted to bullying. Of these, 7% bullied daily, 13% bullied once a week and 80% indicated that they bullied less than once a week. However, 38% of the sample identified themselves as victims of bullying over the previous year, with 19% indicating that they had been targeted daily or weekly (Cross et al., 2006).

To date, a great deal of research effort has been focused on classifying bullying experiences into one of three categories, namely, victim, bully-victim and bully (Buxton, Potter, & Bostic, 2013). In this regard, victims are characterized as passive, physically weak and unpopular individuals who manifest signs of low self-confidence (Eslea & Smith, 2000), depression, anxiety, various psychosomatic complaints (e.g., headaches, stomach-aches and sleep problems) (Fekkes, Pijpers, & Verloove-Vanhorick, 2004), and perform poorly at school (Ttofi, Farrington, Lösel, & Loeber, 2011).

Child victims of bullying tend to describe the bullies in negative terms rather than expressing the reasons why they were a bullying target (Green, Felix, Sharkey, Furlong, & Kras, 2013). Bully-victims, are the group of students who are at most risk of negative psychological outcomes given they often engage in thoughts of self-harm and suicide ideation (Kim, Koh, & Leventhal, 2005) and, tend to experience problems forming friendships (Holt, Finkelhor, & Kantor, 2007). Moreover, many bully-victims display non-compliant behaviours and, thus, are more likely than students in the other two categories to be diagnosed with a childhood disorder (e.g., ADHD, Conduct Disorder or Developmental Delay) (Nordhagen, Neisen, Stigum, & Kohler, 2005).

In contrast, bullies tend to experience longer-term negative psychosocial outcomes. Other research has shown bullies are also more likely than non-bullies to have low I.Q. scores, be disruptive, display dishonest tendencies (Farrington & Baldry, 2010); manifest poor emotional self-regulation (Garner & Hinton, 2010), have mental health problems (Slee, 1995), engage in substance abuse, fighting (Nansel, Overpeck, Saluja, & Ruan, 2004) and receive a criminal conviction by the time they reach adulthood (Olweus, 1999). In addition, research by Farrington (1993) demonstrated that not only are adolescent bullies prone to continuing their bullying behaviours into adulthood, but they are also more likely to have children themselves who bully.

Purpose of the present study

Whole school intervention programs are commonly established to reduce the number of bullying incidences and improve the learning and social outcomes of victims, bully-victims and bullies. While these approaches typically involve students, teachers and parents, they are generally a *top down* model that concentrates on the school's handling of bullying behaviours rather than a *bottom-up* bullying approach involving parents. As such, it is posited that intervention bottom-up programs that are aimed at mothers of accused bullies may be a more effective method of reducing bullying. The rationale being that if one bully can be stopped from bullying through their mother's influence, then a potential exists to stop numerous other children from being victimized by that one bully. One difficulty in designing anti-bullying

programs targeted at assisting mothers to deal with their child's bullying behaviour is that scant research exists that details the impact that a bully's behaviour has on their parenting abilities. This chapter aims to address this knowledge shortfall by investigating the resilience and decision making abilities of mothers. The underpinning hypothesis being resilience, coping skills, social supports and decision-making outcomes will all be poorer in mothers whose child have been accused of bullying than in mothers whose children have not been accused of bullying. If proven, then future intervention programs may need to specifically target these lack of skills.

METHOD

Participants

Participants were mothers of school-aged (5–17 years) children (n=157), with mothers of children not accused of bullying (n=123) and mothers of accused bullies (n=34). The average age of the mothers was 36.5 years, 80% had a post-high school qualification and the majority were middle-class Caucasians.

Variables

The independent variable of child bullying status consisted of two levels; mothers of accused bullies and mothers of children not accused of bullying. The dependent variables were resilience, coping-skills, social support and decision-making abilities.

Materials

The survey comprised four self-reporting surveys, the Individual Resilience Scale (Harms, Pooley, & Cohen, 2012), the Brief COPE (Carver, 1997), the Multidimensional Scale of Perceived Social Support (MSPSS) (Zimet, Dahlem, Zimet, & Farley, 1988) and the Decision Outcome Inventory (DOI) (Bruine de Bruin, Parker, & Fischhoff, 2007). In addition, background questions were asked to gain insight into the participants, namely age, level of education, socioeconomic status, marriage status, number of children and if they themselves had been accused of being a bully as a child. Participants were required to complete the questionnaire online using the Qualtrics software program.

Resilience: Individual Resilience Scale: The Individual Resilience Scale (Harms, Pooley, & Cohen, 2012) consists of 12 questions that reflect a person's overall resilience to situations. Questions such as "when I think about my future, I feel positive" are rated using a seven-point scale, ranging from 1 (strongly agree) to 7 (strongly disagree), which are then calculated to give a total score for resilience.

Coping Skills: Brief COPE: The Brief COPE (Carver, 1997) focuses on individuals' coping resources. It consists of 28 questions on a four point Likert scale, paired together to reflect 14 subscales of coping, namely self-distraction (items 1 and 19), active coping (items 2 and 7),

denial (items 3 and 8), substance use (items 4 and 11), use of emotional support (items 5 and 15), use of instrumental support (items 10 and 23), behavioural disengagement (items 6 and 16), venting (items 9 and 21), positive reframing (items 12 and 17), planning (items 14 and 25), humour (items 18 and 28), acceptance (items 20 and 24), religion (items 22 and 27) and self-blame (items 13 and 26). These subscales are rated from 1 (“I wouldn’t do this at all”) to 4 (“I would do this a lot”) after reading a specific scenario, for example ‘I would say to myself “this isn’t real”’.

Social Support: The Multidimensional Scale of Perceived Social Support: The MSPSS (Zimet, Dahlem, Zimet, & Farley, 1988) measures the support of family, friends and significant others with questions such as “there is a special person who is around when I am in need”. It uses an algorithm, with the 12 items calculated to give a score of high acuity (69-84), moderate acuity (49-68) or low acuity (12-48) on a seven point Likert type scale, ranging from 1 (strongly disagree) to 7 (strongly agree). The higher the score, the better the participant’s perceived social support, and again supports resilience. The scale is designed to distinguish between social support provided by family (items 3, 4, 8, 11), friends (items 6, 7, 9, 12) and significant others (items 1, 2, 5, 10). Good internal reliability has been found to be in the range of 0.72 to 0.85 (Zimet et al., 1988). Canty-Mitchell and Zimet (2000) also found the scale to be valid and reliable.

Decision-making outcomes: Decision Outcome Inventory: The DOI, (Bruine de Bruin, Parker, & Fischhoff, 2007) assesses the participant’s decision-making outcomes, and fundamentally, their avoidance of negative decisions in real life situations. Of the 41 negative decision scenarios, such as “Been in a public fight or screaming argument”, to which the respondent answers yes or no the total number of negative decisions are counted. Reliability has been found to be good with a Cronbach alpha of 0.88 (Bruine de Bruin et al., 2007).

Procedure

After ethical approval had been granted by the Edith Cowan University, mothers of school-aged children were recruited via emails and social media notifications, with the intention of a snowball effect. An information letter was attached to the emails that explained the purpose of the study and that questionnaire was anonymous and the participant could stop the survey at any time. However it was stipulated though that consent would be deemed to be granted upon submission of the survey. Eligibility was emphasised in the opening statement of the survey that only mothers of school-aged children need to respond. A link to the survey via the software Qualtrics was included in the information letter, with the participant needing to click on the link to commence.

The questionnaire took approximately 10 minutes, could be completed at a time convenient to the participant and was returned to the researcher online. Once all data was collected, mothers were allocated to either the accused bully or non-accused bully group, depending on the mother’s response to ‘has your child ever been accused of bullying?’

Participant’s responses were calculated for each scale and also for each individual subscale for coping skills. Once categorized and calculated, the analyses were conducted using SPSS.

Analysis

A between subjects design was used, enabling the researcher to test the hypotheses using independent sample *t*-tests between the two groups (i.e., mothers of bullies and mothers of non-bullies) and their resilience, coping skills, social support and decision outcomes. Pearson’s chi-square was used to determine whether age was related to the mother’s bullying group status.

Hypotheses

It was hypothesized that mothers of accused school-aged bullies would have:

- 1) Lower resilience
- 2) Poorer coping skills
- 3) Lower perceived social support
- 4) Poorer decision-making outcomes than mothers of children not accused of bullying

Figure 1: Mean of resilience, coping skills, social support and decision outcomes of mothers of accused and mothers of children not accused of bullying school-aged bullies. Error bars reflect standard deviation.

RESULTS

Independent sample *t*-tests were conducted using SPSS to examine whether differences existed between the resilient abilities and decision-making outcomes (See Figure 1) of mothers of accused bullies compared to that of mothers of children not accused of bullying. As shown

in Table 1, there were discrepancies in the mean age between groups, therefore a Pearson's chi-square test of contingencies was used to identify whether having a child bully or not was related to age. Age groups were subsequently merged to ensure that more than five mothers were included in each cell.

The chi-square test was not significant, $\chi^2 (3, N=155) = 7.502, p=057$, therefore, age and bullying group were not related.

Table 1: Description of participants by bullying group

	34 mothers of children accused of bullying %	123 mothers of children not accused of bullying %
Age		
Under 30	0	2
30 – 34	11	9
35 – 39	31	53
40 – 44	47	23
45+	11	12
Family		
Married	88	92
Has only one child	28	10
Socio-economic status		
Low	4	10
Middle	63	67
High	33	23
Education		
High school	15	8
College/Tafe	35	19
University	50	73
Accused of bullying as a child	24	5

Resilience

An independent sample *t*-test was used to determine the difference between resilience in mothers of accused bullies ($n=34$) to that of mothers of children not accused of bullying ($n = 122$).

Levene's test indicated unequal variances ($F=8.795, p=004$); therefore degrees of freedom were adjusted from 154 to 43.

Results showed a statistically significant difference in resilience, $t (43) = -2.241, p=030$.

Thus, mothers of accused bullies ($M=70.56, SD=9.189$) had lower resilience than mothers of children not accused of bullying ($M=74.34, SD=6.718$). Cronbach's alpha for reliability was high, .926.

Table 2: Descriptives for the Brief COPE subscales

Brief COPE	M		SD		t	p
	AB	NB	AB	NB		
SD	3.67	3.60	1.726	1.514	.223	.824
AC	6.94	7.20	1.476	1.280	-1.021	.309
Denial	2.79	2.70	1.610	1.135	.401	.689
SU	2.68	2.56	1.276	1.106	.537	.592
UES	6.15	6.18	1.500	1.537	-.107	.615
UIS	6.53	6.76	1.436	1.426	-.799	.425
BD	2.26	2.46	.666	.946	-1.36	.177
Venting	4.73	4.82	1.790	1.528	-.286	.775
PR	4.94	4.52	1.705	1.591	1.329	.186
Planning	7.03	7.21	1.132	1.060	-.826	.394
Acceptance	5.70	5.45	1.551	1.249	.854	.398
Religion	2.64	3.09	1.141	1.699	-1.445	.150
Self-Blame	4.59	4.45	1.794	1.564	.458	.648

Note: Mean (M), Standard Deviation (SD), t-value (t) and significance (p) for the Brief COPE Subscales (SD = Self Distraction, AC = Active Coping, SU = Substance Use, UES = Use of Emotional Support, UIS = Use of Instrumental Support, BD = Behavioural Disengagement, PR = Positive Reframing) for Accused Bully (AB) and Non-Bully (NB) Mothers.

Coping

There appeared to be no significant differences between the two groups (mothers of accused bullies, $n=34$, $M=62.85$, $SD=6.519$; mothers of children not accused of bullying, $n=123$, $M=64.21$, $SD=8.726$) in overall coping, $t(155)=-.844$, $p=.400$. The subscales' internal reliability ranged from .57–.90 (Carver 1997) with similar findings in parents of children .54–.93 (Benson 2009). The present study's internal reliability was .769 using Cronbach's alpha.

Coping Subscales: When using the Brief COPE subscales, humour showed a statistically significant results $t(70)=-2.684$, $p=.009$, after Levene's equality of variances were not assumed ($F=8.989$, $p=.003$), degrees of freedom were adjusted from 154 to 70. Mothers of accused bullies ($M=2.70$, $SD=1.212$) were found to use less humour than mothers of children not accused of bullying ($M=3.40$, $SD=1.712$). However no other significant findings were found for the other subscales of the Brief COPE (see Table 2).

Social support

Social support was perceived by mothers of accused bullies ($M=70.44$, $SD=9.494$) similar to mothers of children not accused of bullying ($M=73.57$, $SD=10.449$), $t(155)=-1.575$, $p=.117$. Reliability measures overall were high (.937) using Cronbach's alpha.

Social Support Subscales: When analysing the social support subscales there were insignificant findings for the perceived social support subscales of significant others, $t(155)=-.764$, $p=.446$, and family, $t(155)=.560$, $p=.76$, however there was a statistically significant result for friends, $t(155)=2.757$, $p=.007$. Therefore mothers of accused bullies ($M=21.94$, $SD=4.403$) perceived social support of friends to be less than that of mothers of children not accused of bullying ($M=24.13$, $SD=4.010$) (See Figure 2).

Decision-making

There were no significant findings for the decision outcomes of mothers, $t(155)=-.009$, $p=.993$, suggesting that the decision-making outcomes for both mothers of accused bullies ($M=8.88$, $SD=3.650$) and mothers of children not accused of bullying ($M=8.89$, $SD=7.374$) are equal. Cronbach's alpha for reliability was .789.

Error bars reflect standard deviation.

Figure 2: The mean for each of the subscales of MSPSS comparing mothers of accused bullies to mothers of children not accused of bullying Error bars reflect standard deviation.

DISCUSSION

Using quantitative data from mothers of school-aged children; resiliency, coping skills, social support and decision-making outcomes were compared between mothers of accused school-aged bullies and mothers of school aged children not accused of bullying. The overarching hypotheses suggested that the resilient abilities and decision-making outcomes of mothers in the accused group would be less than that of mothers of non-bullies. The results from the current study found that of the abilities and skills, only resilience was significantly less in mothers of accused school-aged bullies than mothers of children not accused of bullying. Although there were no overall differences between the two groups in coping skills, perceived social support and decision-making outcomes, the Brief COPE subscale of humour and the MSPSS subscale of friends revealed significant findings. Such findings therefore suggested that humour was used less, and that the perception of social support from friends was less in the accused school-aged bully group than that of the non-bullying group. Thus, the following section will endeavour to discuss the current findings for the resilient abilities and decision-making outcomes of mothers of accused school-aged bullies, with reference to the theory of social identity, as well as the implications for bully intervention programs. Secondly, limitations to the study will be identified with suggestions for future directions, and lastly, a summary of the study.

Resilient abilities

The present study found that mothers of accused school-aged bullies were significantly less resilient, and thus less likely to adapt to adversity than mothers of children not accused of bullying. It is believed that an individual's resilient abilities may be affected by the severity of the situation and the amount of support available (Cicchetti, 2010). Indeed, the accusation that a child is deemed antisocial may possibly constitute a highly stressful situation and therefore impact on a mother's resources. Such high stress levels can therefore result in maladaptive functioning for the mother, as individuals possessing resilient attributes, namely adequate social support, effective problem-solving skills, positive self-esteem and competence, are more adaptive to life's stressors than those who possess fewer attributes (White, Driver, & Warren, 2010). Hawley and DeHaan (1996) confirm that openness, positivity and support were crucial for maintaining resiliency.

As resilience requires effective modifications to one's self-esteem, social support and coping mechanisms (Dumont & Provost, 1999), it was not surprising then that there were significant differences in the various subscales. Although coping strategies appeared to be consistent amongst the two groups in the current study, the Brief COPE however, was not designed to be used as an overall measure of coping (Carver, 1997). While the majority of the subscales were not significant, the use of humour as a means of coping was found to be significantly less in mothers of accused school-aged bullies. The research showed that mothers of accused school-aged bullies were less likely to use humour as a coping mechanism than mothers of children who have not bullied. Humour is a positive emotional-focused coping strategy that reduces the stressor through feelings (Benson, 2009). Not seeing the humour in a stressful situation may increase the severity of the stressor on the individual and subsequently

affect parenting behaviour, which in turn, may contribute to the repeated bullying behaviour of the child (Martin, 2007). Using humour protects the self, and one is therefore more likely to attribute the stress to an external factor rather than to personal failure (Geisler & Weber, 2010). In a crisis, however, mothers often describe their coping skills as changing from a personal concern to that of the concern of others (Cohen, Slonim, Finzu, & Leichtentritt, 2002). It has also been suggested that humour, especially in women, shields an individual particularly from the negative repercussions of stereotypes, which is important with regards to antisocial behaviour (Ford et al., 2004). Jevnikar's (2007) findings support that the use of humour in times of stress resulted in more positive parenting behaviour and therefore more positive family functioning. Hence, individuals who use humour as a coping strategy are more likely to be emotionally stable and show less signs of depression and anxiety (Martin, 2007). Furthermore, Ford, Ferguson, Brooks and Hagadone (2004) found that stereotypical threat was reduced particularly in women who use humour.

In addition to coping strategies, social support is also an important component of resiliency (Haynes, 2005). Social support incorporates more than merely emotional support from others; it also provides confirmation about a person's actions, as well as information and feedback about the individual (Procidano & Heller, 1983). Perceived social support also impacts on others around them, and therefore acts as a buffer to negativity by minimising the effects that stress has on a person's wellbeing (Lazarus, Kanner, & Folkman, 1980). Thus, a mother who possesses an adequate perception of social support is more likely to cope more effectively, which in turn, is beneficial for the child's general wellbeing (Lazarus, Kanner, & Folkman, 1980). It has been found that positive parenting and the perception of adequate social support correlated highly (DeGarmo et al., 2008) and such a relationship may help to reduce child delinquency (Ghazarian & Roche, 2010). Therefore, the current finding is surprising. However, one explanation may be due to the school-aged bully being related to the significant other and family of the mother, and therefore it would be assumed that the father, the grandparents and the like would be highly supportive of the mother with regards to the child's bullying behaviour. Friends however, are removed from familial involvement and thus have no affiliation, or for that matter, loyalty. The significant finding for the social support subscale friends revealed that mothers of accused school-aged bullies perceive social support from friends to be less than that of mothers of children not accused of bullying. As social support from friends was found to be associated with a greater sense of life satisfaction and mental wellbeing, this has concerning implications for the mother of an accused bully (Ekas, Lickenbrock, & Whitman, 2010). Such a lowered perception may be owing to friends, including other school mothers, who may be protective of their own child and therefore their child's selection of school friends. Judgmental views and stereotypes of the accused bully child may be made by other mothers, which could result in the accused child's mother being stigmatised, and subsequently ostracised from the school mothers' in-group.

The impact of bullying on the mother's social identity

Having a child bully may therefore impact the resources, self-esteem and social identity of the mother. Limited research has been conducted on the effects antisocial behaviour has upon the mother with respect to resilience, and furthermore, how the bullying behaviour then transfers to the mother's self-esteem and social identity. SIT (Social Identity Theory) suggests

that people strive to maintain a positive image of themselves and continue to do so by believing that their group is superior to that of another group, affirming self-esteem (Stangor & Jost, 1997). People are motivated to defend their social identity as it threatens self-esteem (Ellemers et al., 2002). Research has suggested that when self-esteem is lowered, resilience decreases (Karatas & Cakar, 2011) and ineffective coping strategies are adopted (Lane, Jones, & Stevens, 2002). Additionally, when resilience is lowered, the likelihood of having a delinquent child increases (Travis & Combs-Orme, 2007), supporting the findings of the current study.

In light of this, what needs to be considered, however, is the sequence of events that emerge for the mother of an accused school-aged bully prior to the bullying accusation. Firstly, the mother identifies herself as the mother of a school-aged child and therefore establishes group membership. Such a valued membership enhances the mother's self-esteem (Tajfel & Turner, 1979). Time passes and group membership remains, that is until the bullying accusation causes uncertainties to be raised over the child's behaviour and consequently, the actions of the mother. Such doubts may be due to the child's antisocial behaviour being a reflection on the mother as a person, as well as her parenting skills. Essentially, it is very easy for others to lay blame on the parent for the child's action. Accordingly, other mothers may then react out of concern for the welfare of their own child and, thus, the social identity of the accused bully's mother may be jeopardised (Crocker & Major, 1989). If a person's social identity challenges that which society considers normal, an individual may be stigmatised (Goffman, 1963), and such a stigmatisation may be the result of the mothers of children not accused of bullying wanting to heighten their own social identity and self-esteem as well as confirm their own beliefs, thereby reducing interactions with the mother of the accused bully (Crocker & Major, 1989). As social stigmatisation, or the social devaluation of an individual's attribute, often leads to the discrimination of out-groups (Crocker and Major 1989), the negative stigma associated with a child bully as being a social deviant may then transpire to that of the parent and in turn cause the mother to be ostracised (Goffman 1963).

Ostracisation is further highlighted by the findings that suggest a lack of humour increases the risk of increased social stigmatisation (Ford, Ferguson, Brooks, & Hagadone, 2004). The mother is stigmatised for the actions of the child and subsequently ostracised to reduce the impact it may have on the social identity of mothers of non-bullies. As social support from friends is perceived to be less, defensive mechanisms to preserve self-esteem result in the use of less humour, therefore impacting on the mother's resilience, which in turn causes greater rejection from the in-group. Therefore, having well developed coping strategies and available social support may help to reduce the negative effects social exclusion has on a person's physical and mental health (Herrman, et al., 2011). Unfortunately, it is human nature to protect one's own social identity, and through the research reviews and the present findings, it seems clear that mothers of accused bullies need support and reassurance rather than exclusion and judgment.

Implications for bullying intervention programs

A compounding situation is, however, that low resilience in mothers increases the likelihood that a child may develop behavioural problems and, thus, the cyclic nature of the bullying behaviour may continue. Such a claim is supported by research conducted by Travis and Combs-Orme (2007), who state that a mother is more likely to have a child with

behavioural difficulties if they are less resilient. Therefore, intervention programs targeting mothers of accused school-aged bullies would be beneficial, not only for the mother but also for the child. With a definite gap in knowledge regarding a mother's resiliency and their child's bullying behaviour, the strong findings from the current research have clear implications for both the school and family environment. At a school level, it may provide teachers, principals and school psychologists with information on the importance and the abilities of the mother when dealing with the issue of bullying. At a family level, it may increase mother's awareness of the role she may have in the antisocial behaviour of her child. As the current study revealed, mothers of accused school-aged bullies had lower resilience, showed little humour in coping and perceived friendship groups to be less supportive. Establishing intervention programs focusing on a mother's resilience may be beneficial in attempting to combat childhood bullying. Numerous studies have been conducted to assess bullying intervention programs, with Farrington and Ttofi's (2009) meta-analysis of 44 anti-bullying programs identifying 17 as successful in significantly reducing bullying behaviour in schools by as much as 20%. Therefore it may be apparent that any type of intervention is better than no intervention at all. Although it has been suggested that bullying may be on the decrease, regrettably though, children are still being peer-victimised. Thus, every effort should be encouraged to try and combat, and reduce, such meaningless and harmful behaviour.

Furthermore, helping mothers to cope with and respond to the bullying incidences of their children, and teaching techniques on how to effectively handle the situation is pertinent, rather than stigmatising and ostracising the mother. Therefore, intervention programs should begin as early as possible, as those implemented during the primary school years are found to be more successful in changing children's behaviours (Rigby, 2003). Evidence assumes that resilience can change, as shown by Proudfoot, Corr, Guest and Dunn's (2009) study using cognitive behavioural training (CBT). Although no known resilient intervention programs have been applied to mothers of children accused of bullying, one particular program was developed for substance abusing mothers to enhance resilience and improve parenting practices (Suchman & Luthar, 2000). The Relational Psychotherapy Mothers' Group (RPMG) clinical program was designed to assist with strengthening the mother's parenting skills by focusing on themselves and their parenting. Identifying and addressing the mother's resilient abilities, effective coping mechanisms and parenting skills, the mother's involvement with their child increased and there was a reduction in child issues. Furthermore, parental involvement in bullying prevention significantly helps in lowering the prevalence of bullying (Farrington & Ttofi, 2011), with Buxton, Potter and Bostic (2013) suggesting that parental involvement in intervention programs to reduce a child's bullying behaviour should focus on empowerment, and teach the parent to strengthen empathy and cooperative behaviours. Parents must also be encouraged to adopt discipline that does not involve physical means or negative reinforcement to avoid the transmission of undesirable behaviours through imitation (Buxton, Potter, & Bostic, 2013). Not only could intervention programs for mothers of accused bullies be imperative in building a mother's resilience, it may also be beneficial in reducing the transmission of bullying behaviours.

Past research findings have suggested that adults who bully are more likely to have children who bully (Farrington, 1993). An interesting finding from the current study was the high prevalence of mothers of accused bullies also identifying themselves as also being accused of bullying as a child. From the qualitative questions, 24% of the mothers of the accused bullies stated that they too had been accused of bullying as a child, compared to only 5% in mothers

of non-bullies. Although the reason for antisocial behaviour is debatable, the combination of heritability and environmental factors may be influential, and therefore may predispose a child to such behaviours. Olweus (1994) claimed that bullies are typically from families who are emotionally and physically aggressive and therefore such aggressive behaviour may be imitated (Nation, Vieno, Perkins, & Santinello, 2008). It has also been suggested that children who display antisocial behaviour are often not disciplined correctly, or disciplined with inappropriate punishments, thereby reinforcing negative behaviour. Such negative behaviour is then considered appropriate to be used by the child.

LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

Several limitations of the current research should be acknowledged. Firstly, as the present study focused on the stigmatised antisocial behaviour of bullying, it therefore had the potential of bias responses from the participants due to the use of self-report measures. Under-reporting on scale measurements may be apparent to avoid the social stigma attached to the label of being a bully (Furlong, Sharkey, Felix, Tanigawa, & Green, 2010). A mother may also be reluctant in accepting that their child is a bully, and therefore did not correctly identify herself as a mother of an accused bully. Secondly, misinterpretations of the term bully may have caused a mother to unintentionally consider their child's inappropriate actions to be merely childhood behaviour. Thirdly, the current research did not take into consideration the length of time between the bullying incident or incidences, or the frequency of the bullying by the child; thus, all that can be determined was the mother's resilience at the time of the questionnaire. Fourthly, decisions made by mothers were consistent across the two groups. The similarity in findings may be due to the DOI asking questions about the participant's decisions over the past 10 years, and therefore it may have been more relevant to ask over the past five years to ascertain current decision-making outcomes, as the mothers may not have had children 10 years ago and decision choices may have been different. Lastly, this paper was not able to establish if these abilities and skills were a result of the bullying incident or if they were prevalent prior to the incident. These could consequently be topics covered in future research.

The findings from the current study indicate that there may be a link between bullying behaviour and the resources of mother's and therefore further research is required. However, it was undetermined from this study if a mother's resilience was already low prior to the bullying incident. Potentially, a longitudinal study on Kindergarten mothers could be conducted using the same questionnaires to determine the resilient abilities preceding a bullying accusation, then re-administered after a bullying incident. Such an investigation may allow the researcher to determine whether a mother's resilient abilities were affected by their child's unacceptable behaviour. Follow-ups could then be administered half yearly to examine how, and if, resiliency changed over time.

CONCLUSION

Whether or not a mother may influence a child's bullying behaviour prior to or after the incident is controversial, however, any effort to try and combat such behaviour is imperative in

helping children avoid such harmful situations and psychological repercussions. The aim of the current study was to identify whether the resilient abilities and decision-making of mothers of accused school-aged bullies outcomes were lower than those of mothers of children not accused of bullying. The findings revealed that resilience, the use of humour and the perception of friends as social support are significantly lower in mothers who have had a school-aged child accused of bullying. These findings therefore suggest that there may be inadequacies in the abilities of mothers of accused bullies, and with appropriate maternal interventions, bullying behaviours might be reduced. Previous literature revealed bullying is a major social concern among children and as bullying appears to originate out of the home environment, the concerning issue is that most interventions are aimed at the school environment. Such programs focus on educating students to recognise bullying, who are then taught how to deal with the actions of bullies (Brank, Hoetger, & Hazen 2012). Programs aimed at parents, primarily mothers, have been minimal.

RECOMMENDATIONS

In conclusion, as the results from the present study indicated that the resilient abilities of mothers might be impacted upon by having a child bully it is recommended that mothers' resilient traits could be best improved through intervention programs that include:

- Addressing the behaviours of bullies and how these can be modified with maternal information sessions and management programs such as the Triple P Parenting Program (Sanders, 1999).
- Increasing the mother's self esteem and resilience through individual counselling sessions which focus on optimism, problem solving skills and goals such as the FRIENDS program (Barrett, 2011)
- Instigating relaxation/meditation/fitness classes for the mothers (Dobbin, 2014).

ABSTRACT

This chapter focuses on analyzing the problem of bullying, an issue that is currently of great concern to parents, teachers, students, the educational community, and also social scientists, governments, and administrations. The social awareness of the seriousness of bullying and its consequences on the victims has been increasing in recent decades in different American and European countries. Fortunately, occasions when threats and fights between students are described as “kid stuff” or “natural and unavoidable situations” are becoming rare, as these acts are getting more attention from adults in schools in order to prevent situations of harassment and act as quickly as possible against the violent situation. This chapter describes, first, the defining characteristics of bullying and the different types of harassment at schools committed by students, mainly adolescents. Then, existing data on the prevalence of the problem are discussed, and the consequences of bullying for victims and the educational community in general are analyzed. Finally, the main individual, family, and school risk factors favoring the appearance of these serious behavior problems in the adolescent period are commented on.

INTRODUCTION

Bullying involves an act of physical or psychological persecution carried out by one student (or group of students) against another student, who is chosen as a victim of repeated attacks (Olweus, 2006). The victim, moreover, is not able to leave this situation by him- or herself. An

aspect that should be clarified is that not every aggression by one student against another constitutes a case of bullying. A punctual fight or insult between two students is a totally reprehensible conduct that should not be allowed in a school context. However, if it is a punctual situation in which there is no inequality of power or force between the aggressor and the victim, it is not considered bullying.

In the school context, there are also other forms of violence, for example, vandalism involving breaking windows, doors or material, punctual insults among students, or serious breaches of discipline. *School violence* is a broader term than bullying, referring to all the aggressive behaviors carried out at schools whose protagonists are students or teachers. Bullying is a specific type of school violence carried out among students and characterized by the intentionality of harm, the persistence of the situation of harassment, and the imbalance of power between aggressors and victims (Olweus, 2013).

However, having clarified what bullying is, it is important to know its different types. In general, physical, verbal, and relational bullying are usually differentiated (Bradshaw, Waasdorp, & Johnson, 2015). *Physical bullying* includes situations in which the victim receives repeated physical assaults—such as slapping the neck, kicking, pushing, pinching, hitting or beating up—by classmates. In *verbal bullying*, the repeated aggressions received by the victim from the classmates consist of insults, humiliations, or the use of derogatory nicknames. *Relational or social bullying* is characterized by repeated situations of social rejection, marginalization, or spreading malicious rumors in order to socially isolate the victim. The victim is excluded from any group activity, in order to isolate him or her from the rest of the students.

Other researchers differentiated between two types of bullying: *direct* or *indirect bullying* (Agnichia & Miyazak, 2013). In direct bullying situations, the attacker directly confronts the victim, they interact face to face, and both physical and verbal assaults may occur. In indirect bullying, however, there is no direct confrontation between the aggressor and the victim. In this case, the attacker also seeks to hurt the victim, but indirectly; the actions are aimed at harming the victim's circle of friends or perception of group membership. Indirect bullying is therefore similar to the relational or social bullying described previously, as what is sought is essentially to damage the victim's social relations and isolate him or her from the group.

However, bullying should not be understood as a situation in which there are only two actors involved: the aggressor and the victim. It is important to include all the students in the analysis, because many of them are aware of this situation, and their reactions in the face of the bullying suffered by one of their classmates may be very different. Although the first investigations on bullying focused solely on the characteristics of the offender and the victim, it is currently understood as a *group and interpersonal phenomenon* whose analysis should include other students (Salmivalli, 2010). The victim's classmates are usually aware (and are sometimes spectators) of the aggressions (physical, verbal or relational) suffered by the victim and, in the face of this situation, they can assume different stances. Thus, some students may belong to the aggressor's group and might encourage his behavior "laughing at his jokes" or even displaying some admiration, whereas other students may passively observe the situation, perhaps not fully aware of the possible severity of certain forms of aggression, such as insults and rejection, or perhaps due to fear of becoming the target of future attacks. Lastly, other students may show their support to the victim and their rejection of the offender's behavior.

In any case, either as followers of the aggressor, as passive spectators, or as defenders (direct or indirect) of the victim, the rest of the students are a key piece in understanding how

to perpetuate or stop bullying (Camodeca, Caravita, & Coppola, 2015; Monks, Palermi, Ortega, & Costabile, 2011; Salmivalli, 2010).

PREVALENCE OF BULLYING

The prevalence of bullying varies greatly depending on different factors such as the definition of the concept (e.g., whether referring to direct or indirect bullying), the method of data collection (e.g., students' retrospective reports, direct registration of students or teachers, etc.) or bullying frequency (e.g., once a week, one or more times a month, etc.) to determine what is bullying. However, the prevalence data usually range between 5-20% for students who admit having been victims of bullying and between 4-10% for students who acknowledge having participated as aggressors (Monks et al., 2009; Stassen-Berger, 2007). In terms of the prevalence of the different types of bullying, relational and verbal bullying are more habitual among students than physical bullying (Defensor del Pueblo [Ombudsman], 2007; Wang, Iannotti, & Nansel, 2009) but this tends to vary depending on the students' gender and age.

Although it has a lower incidence, physical bullying tends to have serious negative consequences for the physical and psychological well-being of the victims. In addition, these victims are often also the target of other forms of bullying, such as insults and social rejection. However, it should not be concluded that only physical bullying deserves attention, and that verbal or relational bullying do not have equally negative effects for those who suffer them. Indeed, the experience of rejection, marginalization, and repeated insults by classmates provoke, by themselves, lower self-esteem and more depressive feelings in the victims. The consequences of a new form of increasingly frequent bullying, which uses the new technologies (cellphone, internet,...) to assault the victim, are also very negative. It is the so-called *cyberbullying* (Foodya, Samaraa & Carlbringb, 2015), whose victims present such devastating consequences as those of traditional bullying (Buelga, Iranzo, Cava, & Torralba, 2015) and whose presence in developed countries is currently estimated as even higher than that of bullying (Buelga, Cava, Musitu, & Torralba, 2015). As for sex and the different types of bullying, boys usually assault their victims physically and directly, whereas girls use more indirect relational and verbal bullying (Carrera, Fernández, Castro, Failde, & Otero, 2013; Dukes, Stein, & Zane, 2009; Lee, 2009; Popp, & Peguero, 2011). Regarding age, the studies confirm that, at lower educational levels, there is greater prevalence of physical and direct aggression, which are replaced in adolescence by indirect types of aggression, with a significant increase of verbal abuse and social exclusion (Hasekiu, 2013).

CONSEQUENCES OF BULLYING

As mentioned, different agents participate in bullying: perpetrators, victims, and observers. The dynamic that develops between these agents influences the classroom climate. Thus, on the one hand, the interactions between students are more negative, and group trust and cooperation decrease. On the other hand, the teacher-student relationship is more distant, with teachers' actions being mainly aimed at managing conflictive situations and applying disciplinary measures (Ochoa & Peiró, 2010). As mentioned by the teachers, this aspect is

problematic because they have scarce strategies and training to deal with such situations, which makes them feel overwhelmed and unmotivated (Álvarez-García, Rodríguez, González-Castro, Núñez & Álvarez, 2010). Having to focus on managing conflicts, the academic content fades into the background. Thus, bullying situations decrease students' motivation to learn (Totura, Karver, & Gesten, 2014), and it is likely that teachers will limit the use of cooperative methods because there is no climate of trust in the classroom promoting their use. This shows that bullying situations have a negative impact both on interpersonal relations and on the teaching-learning process.

Although bullying does affect the different agents involved in this dynamic, as well as the classroom climate, the teachers, families, and the school, the most devastating effects are observed in the victims. On the one hand, regarding the academic area, if a student is the target of bullying, he or she will have serious difficulties focusing on the acquisition of curricular content, with the consequent deterioration of performance (Totura et al., 2014; Wang et al., 2014). With regard to the possible psychological consequences, we note that, given that the bullying situation is extremely stressful, the victim may present anxious or depressive symptomatology, low self-esteem, and even suicidal ideation (Estévez, Murgui & Musitu, 2008; Stapinski, Araya, Heron, Montgomery & Stallard, 2015; Turner, Exum, Brame & Holt, 2013). There may also be feelings of loneliness and unhappiness (Estévez et al., 2008), insomnia and somatic complaints (headaches or stomachaches, nausea, and vomiting) (Gini & Pozzoli, 2013). We emphasize that the physiological discomfort experienced by these students is not simulated, and that hormonal changes have been found that may be the cause of this distress (Vaillancourt et al., 2008). Among the social consequences, the victims develop more distrust towards others due to the expectation that they may be treated unfairly again in the future, which can interfere with new relationships and friendships (Carney, Jacob & Hazler, 2011).

The severity of these effects depends on the intensity and duration of the bullying, but changes in the behavior of the victimized students are always observed. Does the emergence of these changes necessarily indicate the existence of a bullying situation? No, but these signs should alert teachers and family, as they are indicators that something is wrong with the student. The existence of constant school refusal reveals the possible existence of a bullying situation (Hutzell & Payne, 2012). Early detection and action in such situations is essential, because the victims may present a significant deterioration of their psychological well-being and may need professional support. Table 1 synthetically presents the main consequences of bullying for the victims.

MAIN RISK FACTORS

The diversity of factors analyzed in recent studies (e.g., Atik & Güneri, 2013; de Oliveira et al., 2015; Salmivalli, 2010) and the relative weight of the explanation of bullying situations show that it is a multicausal phenomenon. Thus, it seems that bullying situations occur due to the existence of an accumulation of elements and not to a single specific cause.

Table 1. Main consequences of bullying for the victims

Academic	Psychological	Physiological	Social
Difficulty focusing on schoolwork	Anxious or depressive symptomatology	Insomnia	Less trust in others
Decreased performance	Low self-esteem	Somatic complaints	Expectation of being treated unfairly
	Suicidal ideation		
	Feelings of loneliness and unhappiness		

In this regard, in order to better understand the phenomenon and to address it more effectively, it is necessary to attend to the different factors that may be involved and the relationship between them. Below are the major personal, family, school and sociocultural factors associated with school victimization.

Personal Factors

The personal characteristics of the aggressors have been widely studied (e.g., Barboza et al., 2009; Laeheem, Kuning, McNeil & Besag, 2008).

Thus, aggressors tend to have low academic performance, are little integrated in the academic and school dynamics, have frequently disconnected themselves from the teaching process, and tend to seek a rebellious and transgressional reputation beyond the teacher and the parents' authority. Although the first investigations on offenders indicated that they had low self-esteem, it seems that they do not present a negative self-image in all the facets of their lives. On the one hand, aggressors' self-assessment as students and within their families is rather negative, that is, they present *low academic and family self-esteem*. But, on the other hand, they seem to enjoy some popularity within their group of friends and do not perceive themselves as lacking peer support, so they do not have negative social self-esteem, even though their way of interacting with some of their classmates is inadequate. Regarding their interpersonal skills, it has been suggested that some—but not all—aggressors are especially skilled in manipulating their social environment.

Thus, as well as manipulating their classmates so they will isolate the victim and being capable of assuming leadership in conflictive groups, aggressors will also try to use manipulative strategies with adults, for example, responding evasively and even blaming the victim of the aggression suffered when they are asked about this by teachers or parents. With regard to their physical image, aggressors have a positive physical self-concept, often perceiving themselves as strong. Lastly, a personal factor frequently associated with aggressors is their *low emotional empathy for the victim*, as they do not seem to show any discomfort or guilt as a result of their aggressions.

With regard to the victims, recent works have revealed a number of features showing that certain students are in a situation of increased vulnerability. Thus, students who have certain physical striking characteristics (e.g., obesity) (van Geel, Vedder & Tanihon, 2014), students belonging to ethnic minorities (Felix & You, 2011; Schumann, Craig & Rosu, 2013), students who have a sexual orientation different from that of the majority (Cénat, Blais, Hébert, Lavoie

& Guerrier, 2015), students with any kind of disability or special educational needs (Rose, Simpson & Moss, 2015), and students who have some deficit in social skills (Crawford & Manassis, 2011) are more likely to be victims of bullying. These characteristics that make them “deviate from the standard” may have generated a lower self-esteem in these students, which would be aggravated if they become victims of bullying. Given that these personal characteristics are not modifiable, the only way to prevent bullying situations in these collectives begins, precisely, by recognizing this situation of vulnerability and planning actions in the school to promote respect for diversity and acceptance of individual differences.

It would also be necessary to intervene in the lack of social skills that are often observed in the victims, because students who lack strategies to resolve conflicts peacefully, who cannot express their opinions assertively, or who cannot respond to others' requests and opinions may be involved in bullying situations.

Family Factors

The role of the family is essential for children's personal and social development. In this sense, has been noted that the parenting patterns that predominate in the family can influence the role students play in the dynamics of bullying. For instance, overly authoritarian or permissive parenting patterns, characterized by the existence of either too rigid rules or the absence of rules, can promote the development of children's problematic behavior patterns. Specifically, Papanikolaou, Chatzikosma, and Kleio (2011) revealed that mothers with parenting patterns characterized by applying unjustified punishments (authoritarian style) and that fathers showing indifference to their children's actions (negligent style) are related to being a victim of bullying at school.

Previous research has also found that parents who limit their children's possibilities to make their own decisions, restricting their autonomy and independence, with little fluent communication with the children, and uninterested in their problems and concerns are linked to school victimization (Lereya, Samara & Wolke, 2013; Papaikolaou et al., 2011). This type of family interactions produces more insecure and dependent parent-child relationships, which place the child at risk of becoming a victim of bullying.

Another type of issues such as domestic violence, the existence of psychopathology, or the consumption of alcohol may also be relevant factors for students to become victims of bullying (Boel-Studt & Renner, 2013; Eiden et al., 2010; Lereya & Wolke, 2013). In this sense, it is essential to know the existing family dynamics and to provide the parents with guidelines that allow them to handle parenting situations as effectively as possible, in order to avoid negative consequences like the above-mentioned ones.

School Factors

There are also some factors that directly involve the school, which can increase the likelihood of bullying situations. Schools differ, among other aspects, in their organizational structure, in the way they elaborate the rules of coexistence, and in the type of relationships that are established between students, between students and teachers, and between teachers and families.

Whereas in some schools, more cooperative and positive school climates are generated in which few students are excluded from the teaching-learning process, in other schools, the school climates are more negative, and bullying situations are more likely to arise.

In fact, a *negative school environment* is considered a risk factor for bullying. As noted by Sampascual (2009), in the academic area, climate is determined both by the physical (e.g., distribution of space or students) and the psychosocial aspects (e.g., cohesion among students and teachers' type of leadership) occurring in the classroom. Whereas students' distribution in the classroom can influence the relationships that are generated therein, it is particularly relevant to the dynamics of bullying to attend to the aspects linked to cohesion among the students.

In this regard, previous studies have found that students presenting a *rejected* sociometric status are more likely to be victims of bullying (Serdiouk, Rodkin, Madill, Logis & Gest, 2015). Isolated students who do not have support tend to be the target of bullying situations, whereas having at least one “best friend” and feeling that it is possible to communicate openly with this friend reduces the likelihood of being a bullying victim and the negative effects associated with victimization (Cardoos & Hinshaw, 2011; Fitzpatrick & Bussey, 2014).

The degree of group acceptance is also linked to personal characteristics. In this respect, Inglés, Delgado, García-Fernández, Ruiz-Esteban, and Díaz-Herrero (2010) emphasized that students with social anxiety were classified as rejected by their peers more often than their prosocial peers, which somehow increases their vulnerability to being caught up in the dynamics of bullying.

Thus, presenting difficulties in social interaction is a relevant factor for bullying. When attending to these issues, schools should focus not only on punitive measures but should promote activities requiring cooperation to integrate the students, thereby preventing situations of rejection and exclusion and promoting the acquisition of social skills.

It has also been confirmed that the existence of fluent family-school communication has a positive influence on school climate and on students' academic performance (Castro, Expósito, Lizasoain, López & Navarro, 2014a,b; Papanikolaou et al., 2011). Likewise, it is considered that the parents' involvement in the elaboration of the school's rules of coexistence can improve school climate (Gázquez, Pérez-Fuentes, Lucas & Fernández, 2009).

Social and Cultural Factors

Social and cultural factors that may have an impact on the dynamics of bullying include violent actions on TV, video games, and the internet to which minors have access (Chang et al., 2015; Orue & Calvete, 2012). Thus, for example, images showing situations of armed conflict are becoming increasingly frequent in the newscasts, and many cartoons feature violent actions portrayed in a humorous tone.

In addition, video games are increasingly realistic, and the most violent contents are the most highly accepted among youth. The fact that children and adolescents increasingly master the internet means that they may also be exposed to a greater number of violent contents. If this is not adequately addressed, exposure to this type of content may lead to more tolerant attitudes towards violence and desensitization to the suffering of those who experience these actions, the victims (Wei, 2007).

Table 2. Social, personal, family and school factors related to school victimization

Personal	Family	School	Social
Striking physical features	Authoritarian/negligent parental style	Low family involvement	Exposure to violent content on television, video games and internet
Belonging to ethnic minorities	Limitation in decision-making	Rejected sociometric status	Inadequate interpretation of the violence to which they are exposed
Sexual orientation different from the majority	Restriction of the child's autonomy and independence	Absence of trusted peers	
Presence of disabilities or special educational needs	Influent communication	Low social competence	
Deficits in social skills	Lack of interest in child/adolescent's problems and concerns		
	Domestic violence		

Such violence is even frequently justified in order to obtain whatever one wants, either because one is unaware of the possible consequences for the victims or simply because one considers that “the victim deserves it.” In response to these issues, a social commitment is necessary to rethink the content presented in the media and the way in which it is presented. Similarly, the role of families and teachers is essential to help children and adolescents forge a critical view of violent situations and to restructure the possible misinterpretation of these contents. Table 2 summarizes the main social, personal, family and school factors related to school victimization.

Chapter 114

VICTIMS OF SCHOOL BULLYING: PREDICTORS AND OUTCOMES

Militsa Nikiforou and Panayiotis Stavrinides

School of Sciences, UCLan Cyprus
Department of Psychology, University of Cyprus, Cyprus

ABSTRACT

Over the past few decades a significant amount of empirical and theoretical work has accumulated in the bullying literature. Researchers worldwide used several research methods, different instruments and multiple analyses, trying to provide answers on important issues in relation to victimization. What are the victims' characteristics? What are the main individual and contextual factors that put children at risk for victimization? Do interventions have a positive result on victims? What are the socioemotional outcomes in children who have been victimized? These questions will be at the core of this chapter which aims to bring together current empirical studies and theoretical work utilizing a wide array of victimization literature. Thus, in this chapter we will discuss individual and familial risk factors related to victimization, such as the child's temperament and parenting styles and other parental characteristics that tend to be related to victimization. Additionally, several intervention strategies which have been implemented will be discussed. Finally, we will provide a summary of recent findings in socioemotional outcomes in victims such as the risk for depression and anxiety. In theoretical terms, we will try to bind together the most important research findings related to victimization while also we will try to stress out the fact that victimization could be detrimental for children since research has consistently showed that victims are exposed to short-term and long-term negative consequences.

INTRODUCTION

Victims of bullying are subjected to intentionally repetitive aggressive acts by a more powerful individual or peer group (Olweus, 1993). According to the World Health Organization (2012) bullying is a worldwide concern with an average of 32% of children identified as victims

across 38 countries/regions. Due to its high prevalence rates across the world and the short-term and long-term negative outcomes, it remains a significant challenge for practitioners and policy makers to design and implement efficient intervention and prevention programs against victimization.

Numerous studies have identified three distinct categories of children who get involved in bullying incidents at school: the bullies, the passive victims, and the bully/victims (Austin & Joseph, 1996; Bowers, Smith, & Binney, 1994; Wolke, Woods, Bloomfield, & Karstadt, 2000). Compared to the other two categories (i.e., bullies and bully/victims), victims tend to be insecure, shy, introverted, with low levels of self-esteem (Austin & Joseph, 1996; Schwartz, Proctor, & Chien, 2001). Additionally, victims are usually rejected from their peers and are more likely to become isolated (Georgiou & Stavrinides, 2008). Interestingly, a research study by Eslea and Mukhtar (2000) showed that children who are victimized are usually different in appearance characteristics from their peers. For instance, they may be physically weak or obese, suffer a disability, or belong to a different race or culture.

Prior research has shown that personal and contextual factors (e.g., family, peers, school, and community) play an important role in the development of problem behaviours in children and adolescents (Georgiou, 2008; Loeber, Burke, Lahey, Winters, & Zera, 2000). A meta-analysis by Lereya, Samara, and Wolke (2013) showed that negative parenting behavior is associated with small to moderate effects on victim status at school. Research findings related to familial and contextual risk factors of becoming a victim will be at the core of this chapter.

Moreover, it is well established that children who are bullied at school are more likely to suffer from a range of mental health problems such as depression and anxiety (Arseneault, Bowes, & Shakoor, 2010) and even worse, at some instances, experience psychotic symptoms (Schreier et al., 2009). These consequences in victims will be further discussed in this chapter.

Since bullying seems to affect negatively a significant number of students across countries, school psychologists, researchers, and practitioners attempted to design and implement several intervention and prevention programs in order to reduce victimization's high rates. Dan Olweus, a pioneer in bullying research, initiated the development and implementation of anti-bullying prevention and intervention programs in the Scandinavian countries since the 1970s. Olweus' programs showed that they have been effective in reducing victimization of bullying and sometimes this reduction had exceeded 50% (Olweus, 1997). Until now, several innovative intervention programs have been developed while other scientists just replicated Olweus' programs with a few modifications. Therefore, some of the most efficient programs and their important components will be discussed in this chapter.

INDIVIDUAL RISK FACTORS

Bullying literature suggests that demographic factors and children's prior psychosocial adjustment contribute to the likelihood of being victimized by their peers. Gender and socioeconomic status (SES) are particularly two significant factors that seem to influence children's involvement in bullying. For instance, Olweus (1993) found that boys tend to engage in bullying and be victimized more than girls during the middle school years. However, this finding is not consistently confirmed by other empirical studies that showed that gender is not a significant correlate of peer victimization (Carbone-Lopez, Esbensen, & Brick, 2010; Craig

et al., 2009). Furthermore, research studies documented that victims were more likely to be from low SES (e.g., Tippet & Wolke, 2014), indicating that SES is another risk factor for victimization. On the other hand, other studies indicated little or no association between SES and victims or bully-victims (Garner & Hinton, 2010; Veenstra et al., 2005).

Poor psychosocial adjustment is an important area of individual risk factors for victimization. Specifically, research studies showed that a child's internalizing problems can increase the risk of becoming a victim while also these problems may be the result of being victimized at school, suggesting a reciprocal association between the two (Hodges, Boivin, Vitaro, & Bukowski, 1999; Hodges & Perry, 1999). Internalizing problems may have a more general negative impact on child's behaviour at school. For instance, a child who shows a submissive behaviour and be introverted, it is more possible to be a target for victimization (Hodges & Perry, 1999; Olweus, 1993). Saarento, Kärnä, Hodges, and Salmivalli (2013) found that social anxiety predicted both self-report and peer-report victimization. In line with previous findings, Cook, Williams, Guerra, Kim, and Sadek (2010) showed that victimization was related to loneliness, depression, anxiety, and low self-worth in children and adolescents. On the other hand, this vicious cycle rarely breaks down since children who have been victimized display more internalizing problems later on (Arseneault et al., 2006, Reijntjes, Kamphuis, Prinzie, & Telch, 2010; Zwierynska, Wolke, & Lereya, 2013).

It is widely accepted that difficult temperament is related to children's involvement in bullying incidents. Specifically, a research study by Frizzo, Bisol, and Lara (2013) showed that victimized children scored higher in emotional sensitivity (trauma and rejection sensitivity, sadness) and lower in self-esteem. The same authors also found that victims scored lower in attention and executive functions. Consequently, it appears that victimized children seem to display deficits in emotional and cognitive domains, suggesting that they may have a dysfunctional profile with an extremely difficult temperament.

In addition, some researchers have examined the link between personality and children's involvement in bullying using personality measures such as the Big Five Factor Model. For example, Mitsopoulou and Giovazolias (2015) showed that lower level of Agreeableness and Conscientiousness and higher levels of Neuroticism and Extraversion were associated with bullying and victimization. Specifically, victimization was associated with high Neuroticism and low Conscientiousness. According to Bollmer, Harris, and Milich (2006) children who display negative emotions would be more possible to elicit attacks by peers while also victimized children would be more possible to express negative emotions. Similarly, Slee & Rigby (1993) showed that victimized children tend to score low on extraversion and high on neuroticism.

FAMILIAL RISK FACTORS

Family plays an important role in promoting children's development and socialization process. Therefore, it is essential to identify familial factors that put the child at risk for victimization. One of the most dominant familial factor that is related to victimization is parental style (Baumrind, 1991; Maccoby & Martin, 1983) which describes how children perceive their parents' socialization practices such as the way they respond to their needs (responsiveness) and the way they use control (demandingness) and monitoring. Previous

studies have focused on the relationship between bullying/victimization and parental style (e.g., Georgiou, 2008). Interestingly, Georgiou (2008) found that permissive parental style was positively related to victimization. However, an earlier study by Georgiou, Fousiani, Michaelides, and Stavrinides (2013) showed that authoritarian parental style was positively related to both bullying and victimization. For example, permissive parents who do not set boundaries to their children's behaviour, tend to have children that they feel insecure and are more vulnerable, making them possible targets for victimization by their peers. Similarly, parents who use harsh discipline practices and have excessive demands from their children are more likely to have victimized children (Hay & Meldrum, 2010). In line with these findings, a meta-analysis by Lereya et al. (2013) showed that abuse, neglect, and maladaptive parenting were the best predictors of victimization at school. In general, negative parenting practices tend to affect children in feeling helpless and have less self-confidence (Duncan, 2004). As a result, they generalize the consequences of their adverse experiences at home to the school context. Moreover, Haynie et al. (2001) showed that middle school students with lower perceptions of parental involvement and support were more possible to report past victimization than non-victimized students.

Additionally, a number of studies showed that parental overprotection increases the likelihood of victimization by peers (e.g., Brock et al., 2006). In line with that, Georgiou (2008) also found that maternal overprotection is associated with victimization. It was suggested that overprotecting parenting behaviours may promote the children's dependency to their mother which in turn inhibits the ability to develop adaptive social skills, placing them as easier target for victimization by peers (Berdondini & Smith, 1996; Duncan, 1999; Georgiou, 2008).

Family violence is another risk factor for victimization. According to Finkelhor, Ormrod, Turner, & Hamby (2005), students who experience any form of victimization may be at greater risk for other forms of victimization. Other studies showed that emotional, physical, and sexual abuse were significant risk factors for peer victimization (e.g., Shields & Cicchetti, 2001).

However, Lereya, et al. (2013) found that positive parenting practices are protective against peer victimization. These positive practices include good communication between parents and children, high levels of responsiveness, high levels of parental involvement and support, and adequate levels of parental supervision. The identification of risk and protective familial factors is necessary in order to develop intervention programs that can be applied to the family context.

PEER RISK FACTORS

Peer factors are significant predictors for victimization. Previous studies indicated that victims tend to have fewer friends, poorer peer relationships (e.g., Nikiforou, Georgiou, & Stavrinides, 2013), and feeling less liked by their peers than non-victimized children (Smith, Shu, & Madsen, 2001). Nikiforou, Georgiou, and Stavrinides, (2013) found that victimization is significantly negatively predicted by peer trust and positively predicted by peers alienation. In line with this finding, Powell and Jenson (2010) using a sample of 150 girls found that poor friendship quality with other girls were significantly related to an increased risk of peer victimization. Therefore, victims are not popular with peers, which in turn can increase their likelihood to be rejected. However, friendships can be a protective factor against victimization (Pellegrini, Bartini, & Brooks, 1999).

SCHOOL AND COMMUNITY RISK FACTORS

Findings on the relationship between school factors (e.g., school climate, teachers' attitudes) and victimization have also been reported. Earlier findings suggested that students perceived the shared psychosocial and disciplinary climate at school as negative (Ma, 2002). According to Saarento, Kärnä, Hodges, and Salmivalli (2013) found that victimization was common in classrooms and schools where students perceived their teachers to have less disapproving attitudes toward bullying. That is, the risk of being victimized was less in contexts where students believed that their teachers thought bullying was absolutely wrong. Furthermore, Thornberg and Knutsen (2011) have also suggested that a possible explanation for bullying is poor anti-bullying practices that the teachers apply in schools. In contrast, positive school climate promotes cooperative learning, group cohesion, respect, and mutual trust (Ghazi, 2003); factors that inhibit bullying and victimization.

Further, community factors seem to have a relationship with bullying and victimization. According to Mann, Kristjansson, Sigfusdottir, and Smith (2015) higher levels of community and family connection, community closure, and support reduced the odds of young people engaging in bullying or victimization. Specifically, they found that low levels of community closure and peer support increased the odds of experiencing victimization. That is, in communities that neighbors know their children's friends and children's friends' parents and work with them to coordinate and monitor their children's activities, it is less possible their children to be victimized or bully other children.

INTERVENTION PROGRAMS

Bullying can be seen from a socio-ecological perspective (Espelage & Swearer, 2004), whereas individual, familial, peer, school, and community factors put children at risk for victimization. Hence, most research studies focused on the design and implementation of interventions at the individual and school levels. In this section, a number of intervention programs against victimization and bullying will be discussed. It is essential to identify the most efficient programs, since their wider implication will reduce the rates of victimization and bullying at schools.

One of the initial prevention programs against bullying was introduced by the pioneer in bullying literature Dan Olweus (1997) in Norway and the program was called: Anti-bullying Prevention Program — Norwegian “Nationwide Campaign Against Bully/Victim Problems.” During this two-year school-based intervention program approximately 2500 fourth to seventh grade students were participating from 42 primary and secondary/junior high schools. The program included positive involvement from teachers and parents, firm limits to bullying behaviour and consistent use of non-hostile sanctions on rule violations. Evaluations of this program indicated that the reduction of bullying has exceeded 50%.

Alsaker and Valkanover (2012) presented the Bernese Program against Victimization in Kindergarten and Elementary School (Be-Prox). The basic principle of this program was to develop teachers' ability to address bullying behavior and prevent victimization. Be-Prox was initially developed in 1998 in the frame of a research project. The program consisted of six modules such as: Sensitization: “Subjective attitudes,” Bullying may be hard to detect: “Look

at it,” Rules against bullying: “The contract” and so on. All six modules were designed to change teachers’ attitudes regarding bullying. The evaluation of this program showed that scores on physical and indirect victimization had dropped significantly in the prevention group than on the control group. A meta-analysis by Farrington and Ttofi (2009) showed that Be-Prox was one of the nineteen programs that appeared to be effective in reducing bullying or victimization.

In addition, the Zero Program was introduced by Roland and Midthassel in 2003 but it has its roots in Norway’s work back in 1983. This program has three main principles which are the following: a zero vision of bullying, collective commitment among all employees at the school using the program (school-approach), and continuing work. Furthermore, it lasts for approximately sixteen months. Specifically, this program presupposes that bullying will occur even though we try to prevent it and because of that it suggests that the main teacher of the class has to know how to conduct the intervention against victimization. Midthassel, Bru, and Idsøe (2008) found a positive trend against victimization which was the main achievement of the program period while this trend remained after the follow up two years later.

The KiVa program from Finland is an additional innovative anti-bullying program that was proposed by Salmivalli and Poskiparta in 2006. This program is based on the idea that a positive change in the behaviors of classmates can reduce the rewards gained by bullies and as a result, this will reduce their motivation to bully. It is an innovative program since it used the Internet (specific online questionnaires, ensuring anonymity, and Web-based forums for teachers) and visual learning environments (e.g., computer games related to bullying) to change students’ attitudes about bullying. Some of the main characteristics of the program are the following: classroom discussions, group work among teachers and students, short films about bullying, role-play exercises, and peer support groups for victims of bullying. Additionally, parents were participating in this program by attending lectures during special information nights and by reading guides against victimization and bullying on the internet KiVa webpage. Evaluation of the KiVa program using a large randomized controlled trial including 117 intervention schools and 117 control schools showed that the program reduced both self- and peer-reported bullying and victimization significantly (Kärnä, Voeten, Little, Poskiparta, Kaljonen, & Salmivalli, 2011).

More recently, Espelage, Low, Polanin, and Brown (2013) presented the Second Step: Student Success Through Prevention (SS-SSTP) Middle School Program on reducing youth violence including peer aggression and peer victimization among middle school students. During this program teachers implemented 15 weekly lessons of the sixth-grade curriculum that focused on social emotional learning skills, including empathy, communication, bully prevention, and problem-solving skills. This study showed that the intervention effect was significant. Specifically, it was found that students in intervention schools were 42% less likely to self-report physical aggression than students in control schools. However, there was no intervention effect for peer victimization.

Overall, some of the most important components that have commonly showed significant intervention effects for bullying and victimization are intensity of program for children and teachers, training for teachers, peer support, group work, and parental engagement such as meetings and information for parents. In sum, a whole-school systems-based program rather than a curriculum one could produce more positive results in reducing bullying and victimization (Ttofi & Farrington, 2011).

SOCIO-EMOTIONAL OUTCOMES

A number of cross-cultural studies have documented the widespread frequency and high prevalence of peer victimization both in Western and non-Western societies (Smith, Cowie, Olafsson & Liefvooght, 2002). Peer victimization is linked to a wide variety of social-emotional adjustment difficulties, such as internalizing (i.e., anxiety, depression, withdrawal, and somatic complaints) and externalizing (i.e., aggression, delinquency, and attention difficulties) adjustment difficulties (e.g., Hawker & Boulton, 2000; Leadbeater & Hoglund, 2009).

Previous research studies showed that peer victimization was associated with a variety of adjustment problems such as symptoms of posttraumatic stress (Storch & Esposito, 2003), loneliness, low self-worth, depressive symptoms, suicidal ideation, and borderline personality disorder symptoms (Arseneault, Bowes, & Shakoor, 2010; Hawker & Boulton, 2000; Herba et al., 2008; Troop-Gordon & Ladd, 2005). In line with the previous studies, Stavrinides, Georgiou, Nikiforou and Kiteri (2011) using a longitudinal design found that bullying and victimization at Time 1 were related to an increase of adjustment problems such as emotional problems and a decrease of school achievement at Time 2. Furthermore, another study showed that victimized children reported high levels of internalizing problems such as anxiety and somatization, as well as problematic relationships (Goldbaum, Craig, Pepler, & Connolly, 2003). In the same line, research on cyber victimization showed that externalizing, internalizing, and academic problems were related to cyber victimization (e.g., Tsitsika et al., 2015).

Espinoza, Gonzales, Weisner, and Fuligni (2013) found that chronic peer victimization incidents were associated with heightened distress and academic problems among Mexican-American adolescents. Further, they showed that daily victimization incidents were related to more school adjustment problems (i.e., academic problems). In line with this argument, a meta-analysis by Nakamoto and Schwartz (2010) concluded that victimized students are more likely to earn lower grades and score lower on achievement tests.

Bifulco, Schimmenti, Jacobs, Bunn, and Rusu (2014), using a sample of 160 high-risk community-based emerging adults (age 16-30), found that both types of bullying experiences were associated with parental neglect and abuse, parental discord and inadequate supervision while victimization alone related to internalizing problems such as anxiety disorders and major depression. The participants were interviewed to rate the severity of bullying before age 16. This study showed clearly that victimization could have negative long-term effects on people's lives.

The short-term and long-term effects of childhood victimization on well-being warrant attention. Thus, it is imperative to design and implement prevention and intervention programs against victimization. In the next section, implications for researchers, scholars, policy makers, and practitioners will be discussed.

IMPLICATIONS FOR RESEARCHERS, SCHOLARS, POLICY MAKERS, AND PRACTITIONERS

Policy makers should draw their attention to two aspects of victimization: First, to provide clear documents to schools that will enable teachers to identify and help victims of bullying.

Second, it seems that early prevention should be a priority for policy makers. Prevention programs should address to high risk children, for instance, children that are more vulnerable and introverted because they are different in appearance characteristics from their peers.

Furthermore, training programs for teachers and parents should be developed. Training programs should be informative and provide guidelines of how to handle a bullying/victimization incident. On one hand, teachers and educational psychologists need to identify the signs of bullying and victimization even among preschoolers. Teachers should be able to recognize a bullying incident based on the three criteria (Olweus, 1993), while to be able to detect and support the victims even though in some occasions it is difficult to detect indirect forms of bullying. Fear, social withdrawal, somatic complaints, sudden sadness, reluctance to go to school etc., these might be signs of victimization.

CONCLUSION

The prevalence of victimization is quite alarming as documented by epidemiological studies worldwide. The high rates for victimized children and the short-term and long-term detrimental socio-emotional outcomes stress out the need for the development and the implementation of more effective prevention and intervention programs against victimization. It is important to note that evidence shows that early prevention can bring positive results across a series of challenges many children face while growing up.

The identification of victimized children is essential for teachers and parents. However, it is even of greater significance to convince educational administrators to invest in prevention programs. For example, training programs for teachers and parents should be developed. Also, activities should be integrated in the school program in order to allow children to build positive traits and resilience.

ABSTRACT

Bullying victimization is a serious problem among in-school adolescents. Because of limited reports on bullying among adolescents in Benin, a study was conducted to determine the prevalence and correlates for bullying victimization among school-going adolescents in Benin. Secondary analysis of data was conducted using the 2009 Benin Global School-based Health Survey (GSHS) data. Logistic regression analyses were done to estimate associations between selected explanatory variables and the outcome (bullying victimization). Out of 2,690 in-school adolescents, 49.3% were of age 16 years or older, 66.9% were males and 40.1% reported having been bullied at least once in the previous 30

* Corresponding Author's Email: mazmazli@ yahoo.com.

days to the survey (39.2% among boys versus 42.0% among girls). Male adolescents were 11% (adjusted odds ratio (AOR) = 0.89; 95% confidence interval (CI) 0.88–0.90) less likely to be bullied compared to female adolescents. Participants who drank alcohol were 45% more likely to be bullied than those who did not drink alcohol (AOR=1.45; 95% CI 1.43-1.47). Adolescents who smoked cigarettes were 24% (AOR = 1.24; 95% CI 1.21–1.28) more likely to be bullied compared to non-smokers. Those who reported being involved in physical fighting were 77% more likely to be bullied than those who were not involved in physical fighting (AOR=1.77; 95% CI 1.75-1.79). Adolescents who had parental supervision were 10% (AOR=0.90; 95% CI 0.89, 0.91) less likely to be bullied than those who did not have parental supervision. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

Keywords: bullying victimization, prevalence, correlates, adolescents, Benin

INTRODUCTION

Bullying victimization is a serious problem among in-school adolescents and has a long term effect on problem behaviour in young adulthood (1). Bullying is associated with truancy from school (2) and affects school achievement (3). It has also been associated with health problems (4-7) such as depression and suicidality.

Bullying victimization is a common problem among children and adolescents across the globe. Its prevalence varies across countries partly due to differences in the definition, study design and sample (8). Among 28 European countries, the prevalence of being bullied in previous last year varied from 6% in Sweden to 40% in Lithuania (9). Meanwhile, in 19 low- and middle income countries, the prevalence of being bullied in the previous 30 days ranged from 7.8% in Tajikistan to 60.9% in Zambia (10). In the United States, about 10% of school going children were bullied (11), and in Canada an average of 16% of the children (17.8% of boys and 15.1% of girls (12)) were frequently victimized (13). In Asia, prevalence of being bullied was 27.8% in Thailand (14), 19.0% in Guangdong province in China (15), 8% in Western Turkey (16), 35.5% in Philippines (17), and 14% of the students were bullied in Korea (18). In a study involving 40 countries, Craig et al (19) observed that adolescents in Baltic countries reported higher rates of being bullied, whereas northern European countries reported the lowest prevalence.

Demographic factors have been associated with bullying victimization. In middle-income countries, male gender (10, 20, 21) and younger age (10, 22) have been associated with bullying victimization. Substance use has also been reported to be associated with bullying victimization (23). Tharp-Taylor et al (24) have reported an association between cigarette smoking and bullying victimization and between marijuana use and bullying victimization. Bullying victimization has also been associated with physical fighting (20, 22, 25). Factors associated with bullying victimization have not been consistent across countries partly due to differences in the selected variables for analysis. Hence, it is important that each population establishes risk factors for bullying victimization for use in designing interventions to curtail or prevent bullying.

This study involved further analysis of data from the Benin Global School-based Health Survey (GSHS) that was conducted in 2009. The survey was developed by the World Health Organization (WHO) in collaboration with the United Nations Children's Fund (UNICEF),

United Nations Educational, Scientific and Cultural Organization (UNESCO), and Joint United Nations Program on HIV/AIDS (UNAIDS) with technical assistance from the Centers for Diseases Control and Prevention (CDC), Atlanta, Georgia, United States. The GSHS aims to provide data on health and social behaviours among in-school adolescents. Further details of the GSHS have been reported elsewhere (26). Among the 13-15 years old pupils in Benin, 42.1% (42.7% of boys and 40.7% of girls) were bullied (27). Because this analysis was limited to the 13-15 years age group and no attempt was made to determine factors associated with bullying in Benin, we conducted further analysis of the 2009 Benin GSHS to determine the prevalence of bullying and its correlates in the school-going adolescents in Benin.

METHODS

The Republic of Benin with a population of 9.98 million is located in West Africa, bordering with Togo in the west, Nigeria in the east and Burkina Faso and Niger in the north. The capital city of Benin is Porto-Novo. Literacy (ability to read and write) among persons aged 15 years or older was 55.2% of males and 30.3% of females. The population comprised of 42.8% Christians, 24.4% Moslems, 17.3% practiced Vodun and 6.5% claimed no religion affiliation (2013 census). During pre-colonial era, young boys were often apprenticed to older soldiers, and Benin was characterized by ethnic strife during post-colonial era with six coups between 1963 and 1970 (<http://en.wikipedia.org/wiki/Benin>. Accessed 2014 January 15).

Study design, sample size and sampling

A School-based Health Survey was conducted in 2009 among students in grades 10 to 12 in Benin. A total of 2690 students participated in the survey. The response rate and sampling methods that were used in the survey are described in greater detail elsewhere (27). The school response rate was 100%, the student response rate was 90%, and the overall response rate was 90%. A two-stage cluster sampling technique was used to draw the sample. At the first stage of sampling, schools were randomly selected with probability proportional to enrollment size. At the second stage of sampling, classes were randomly selected and all students in selected classes were eligible to participate.

Data collection

The data set and code book were made available to the public on the GSHS website (<http://www.cdc.gov/gshs/>. Accessed 2014 February 15). The privacy of students was protected by allowing for anonymous and voluntary participation. No school identifier was included in the data that was deposited in the public domain.

The survey obtained information among other subjects on bullying; alcohol use; tobacco use; parental supervision and violence. The questionnaire was self-administered by students. Bullying victimization was the outcome variable. It was explained as follows: "Bullying occurs when a student or group of students say or do bad and unpleasant things to another student. It

is also bullying when a student is teased a lot in an unpleasant way or when a student is left out of things on purpose. It is not bullying when two students of about the same strength or power argue or fight or when teasing is done in a friendly and fun way.” Students were then asked the following question: “During the past 30 days, on how many days were you bullied?” The responses were: 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. Those reporting one or more days were considered to have been bullied. The independent variables were identified from the literature as associated with bullying. The following were the exposure variables that were considered in the analysis:

- Alcohol consumption: the variable was obtained by asking the question “During the past 30 days, on how many days did you have at least one drink containing alcohol?” The responses were: 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. The variable was categorized as having drunk alcohol in the previous 30 days to the survey, if pupil drank 1 or more drinks containing alcohol; otherwise they were categorized having not consumed alcohol in the same period
- Smoking cigarettes: Pupils were asked “During the past 30 days, on how many days did you smoke cigarettes?”; and the responses were 0 days, 1 or 2 days, 3 to 5 days, 6 to 9 days, 10 to 19 days, 20 to 29 days and all 30 days. Smoking cigarettes was categorized into having smoked cigarettes in the previous 30 days to the survey if the pupil smoked cigarettes on 1 or more days in the previous 30 days to the survey; otherwise the pupil did not smoke cigarettes.
- Parental supervision: pupils were asked the question “During the past 30 days, how often did your parents or guardians really know what you were doing with your free time?” The responses were never, rarely, sometimes, most of the time and always. The responses were categorized into having not received parental supervision if they were never supervised; otherwise they received parental supervision.
- Physical fighting: a physical fight was explained as: “A physical fight occurs when two students of about the same strength or power choose to fight each other”. The pupils were asked the following question: “During the past 12 months, how many times were you in a physical fight?” The responses were 0 times, 1 time, 2 or 3 times, 4 or 5 times, 6 or 7 times, 8 or 9 times, 10 or 11 times and 12 or more times. Pupils who were involved in 1 or more times of physical fight were labeled as being involved in a physical fight during the previous 12 months to the survey; otherwise they were deemed as not having been involved in a physical fight in the same period.

Data analysis

Weighted prevalence of the main outcome (bullying victimization) and socio-demographic characteristics were calculated. Bivariate and multivariate logistic regression analyses were done to determine associations between bullying victimization and relevant variables according to the literature.

A weighting factor was used in the analysis to reflect the likelihood of sampling each student and to reduce bias by compensating for differing patterns of non-response. The weight used for estimation is given by the following formula:

$$W = W1 * W2 * f1 * f2 * f3 * f4$$

where

W1 = the inverse of the probability of selecting the school,

W2 = the inverse of the probability of selecting the classroom within the school,

f1 = a school-level non response adjustment factor calculated by school size category (small, medium, large),

f2 = a class-level non response adjustment factor calculated for each school,

f3 = a student-level non response adjustment factor calculated by class, and

f4 = a post stratification adjustment factor calculated by grade.

We report unadjusted odds ratios and their 95% confidence intervals from univariate logistic regression analyses for selected predictor variables while considering having been bullied in the past month as a dependent variable. We also report results from a multivariate logistic regression analysis (adjusted odds ratios and their 95% confidence intervals) to determine independent predictors for the outcome.

Table 1. Socio-demographic characteristics of the study population

%* - weighted percent; n** - unweighted frequency.

RESULTS

A total of 2,690 in-school adolescents participated in the Benin Global School-Based Survey of 2009. For those study participants whose data were available, 49.3% were of age 16

years or older, 66.9% were males and 40.1% reported having been bullied in the past month (39.2% among boys versus 42.0% among girls). Further description of the study sample is given in table 1.

Factors associated with being a victim of bullying

Bivariate and multivariate analyses produced similar results (see tables 2 and 3). In Multivariate analysis, male adolescents were 11% (adjusted odds ratio (AOR) = 0.89; 95% confidence interval (CI) 0.88–0.90) less likely to be bullied compared to female adolescents. The other risk factors that were identified in the analysis were alcohol use, smoking and physical fighting.

DISCUSSION

In this most recent 2009 Global School Health Survey conducted in Benin, 40.1% of the students (39.2% among boys versus 42.0% among girls) reported having been bullied in the previous 30 days to the survey. Subpopulations at increased risk for being bullied were adolescents aged 15 years, female gender, alcohol drinkers, smokers and adolescents who were involved in physical fighting. Meanwhile, parental supervision was protective to being bullied. The prevalence in the current study is alarmingly high, although the lowest as compared to other west African countries.

A total of five countries (Benin, Algeria, Mauritania, Ghana and Senegal) have been participating in the Global School Health Surveys in West Africa (28). Among the 13-15 years-olds, the prevalence of being bullied was the lowest in Benin with an overall prevalence of 42.1% (42.7% among boys and 40.7% among girls) compared to overall prevalence rates of the other West African countries ranging from 47.2% to 58.7% (boys 48.0% to 60.7%; and girls 46.3% to 57.3%). The overall prevalence of 40.1% in the current study which included individuals younger than 13 years and older than 15 years is lower than the 52.3% observed in Uganda (29), 51.3% (54.2% males and 52.2% females) reported in Botswana (30) and 62.8% (60.0% of male and 65.0% of female) reported in Zambia (31). Generally, prevalence estimates for bullying victimization have varied within and between countries, within and between

regions, and within and between continents. These variations may reflect cultural differences in the definitions of bullying (32) and bullying victimization (19).

Associations between bullying victimization and gender have not been consistent. Craig et al (19) observed that rates of victimization were higher for girls than boys in 29 out of 40 that they studied. In the current study girls were more likely to be bullied than boys, contradicting a finding reported in Zambia by Siziya et al. (31). Knowledge on the type of bullying may help in clarifying the sex difference in bullying victimization. If verbal, sexual and relational bullying are the dominant types of bullying in a population, more girls than boys may be bullied. Vieno et al (33) reported that girls were more likely to be victims of verbal, relational and sexual bullying than boys, with the boys being bullies in these forms of bullying.

It was observed in the current study that adolescents aged 15 years were more likely to be bullied than older students. This finding is not consistent with the observations of Craig et al (19) that bullying victimization decreased with age among boys in 30 of the 40 countries, and in 25 out of 39 countries among girls. Craig et al. (19) propose that the reduction in victimization by age may partly be due to age related changes in youth adapting socially as they develop or reflect equalization in physical sizes and consequently, increased effectiveness at inhibiting bullying, and partly it may be due to adolescents who bully may be targeting a fewer number of students with increasing age or targeting younger children. It is not clear why there was no difference in the prevalence of being bullied between adolescents aged less than 15 years and adolescents aged 16 years or older.

Drug abuse facilitates risky situations where bullying can occur. The finding in the current study that alcohol is associated with bullying victimization concurs with findings elsewhere (2, 31, 34, 35). Students who drank alcohol might have found themselves in situations that when drunk they might have been involved in some type of bullying such as physical fighting. Bullying victimization has also been associated with smoking cigarettes (34) and dagga (2, 36). The significant, positive association between victimization and substance use underscores the need to intervene with bullying behaviors among adolescents (37).

The finding that students who received parental supervision were less likely to be bullied in the current study is consistent with the observation made in Beijing by Hazemba et al. (34). This finding is also consistent with the observation by Jeong and Lee (38) who indicated that adolescents with parent support were less likely to be victims of school bullying, and lack of involvement and support from parents is likely to increase the risk of bullying victimization (39). While lack of parental supervision has been associated with smoking (40) and less cohesive family behaviour associated with alcohol use in cross sectional studies, cohort studies are needed to establish the protective effect of the parental supervision. Parents who are not involved in fighting are good role models for their children who may not find themselves in situations where bullying may occur. Furthermore, being under the watchful eye of the parents, adolescents may keep out of trouble.

Students who were involved in physical fighting were more likely to be bullied in the current study than adolescents who were not involved in physical fighting. In another study, a dose response has been observed between bullying victimization and physical fight (41), thus providing more evidence that physical fighting may be an exposure to bullying. Adolescents involved in fighting might have been bullied by older adolescents in retaliation for their involvement in fighting.

Factors associated with bullying victimization have varied between studies partly because of the differences in the factors that were selected for the studies. Hence it is important that risk

factors are determined for the population to be targeted for intervention to curtail or prevent bullying victimization.

Because of the cross sectional study design, we are unable to provide adequate evidence that observed factors are predictive risk factors for bullying victimization. For instance, in the association between alcohol consumption and bullying, adolescents might have consumed alcohol as a result of being bullied. Comparisons of the prevalence in the current study with those obtained in other studies may be biased as a result of differences in defining the term bullying victimization. However, comparisons with results from other Global School Health Surveys are valid as they use the same definition. The major strength of the current study was the large sample size. Responses may have been biased towards socially accepted norms. We cannot rule out recall bias as participants were at times required to recall events that may have happened over a long time ago (1-12 months ago).

In-school adolescents in Benin report a lower prevalence of bullying victimization than other countries in West Africa. Parental supervision and being a male were associated with lower likelihood of bullying victimization; Smoking, alcohol drinking, and physical fighting were associated with a history of bullying victimization. Interventions aimed at promoting adolescents health would benefit from taking these observations into consideration. The information contained in the current study would also form as a baseline data for use in such interventions to curtail or prevent bullying among adolescents in schools.

Chapter 116

BULLYING BEHAVIOUR FOLLOWING STUDENTS' TRANSITION TO A SECONDARY BOARDING SCHOOL CONTEXT

ABSTRACT

This study investigated the prevalence and types of bullying behaviour that boarding students experienced during the transition to a secondary boarding school. Cross-sectional data on 76 male and 74 female boarding students in Grades 7, 8 and 9 was used from a larger longitudinal study of 3,462 students. An examination of the combined dataset prevalence figures found that boarding students reported experiencing significantly higher victimization and perpetration of bullying behaviours than non-boarders after their transition into secondary school. The victimization was found to predominantly take the form of verbal bullying. The increase in the prevalence of bullying behaviours over the course of the first year of secondary school suggests that prior to and during this transition period is the most critical time to implement bullying prevention programs. Due to the sustained nature of bullying behaviour over the first two years of secondary school it is recommended that boarding schools develop clear policies and consistent procedures and practices to address bullying and encourage help seeking behaviours. Similarly these students will need support to build positive relationships with their peers to seek support from others early and often if they are experiencing difficulties.

Keywords: Bullying, victimization, boarding school, adolescence

INTRODUCTION

Adolescence is a developmental stage in life that is associated with major cognitive, emotional, physiological and social change. Adolescence coincides with the onset of puberty and is typically described by parents as a period in which they attune to their child's growing need for autonomy and greater desire to source social support from same aged peers. Many adolescents look forward to the transition to secondary school as it represents a period of possibilities; a time to master new academic, social, emotional and extracurricular activities (1). However, adapting to multiple formal and informal organizational and social relational structures that are inextricably linked with the high school environment can prove particularly daunting to transitioning students (2).

Transitioning from primary school to a secondary boarding school adds another layer of complexity to secondary school life, as students have to simultaneously adjust from a situation where home and school are separate, into a setting where a temporary new home and schooling are merged together. Although some boarding students have reported the transition to boarding school has given them a greater appreciation for family and home, other students have equally reported that the process of adapting to new boarding school duty of care rules and regulations can be difficult as they tend to reduce privacy and personal freedom. Moreover, it commands boarding students to almost instantly display high levels of self-reliance, life skills and independence (3)". Similarly, boarding school requires adjusting from a situation where contact with family members occurs on a daily face-to-face basis to a situation where for extended periods of time contact is limited to contact via telephone, Skype and other means of communication such as email and text messages. Others have also described this change as shifting from vertical relationships with parents to horizontal relationships with peers at school and within the boarding house (3).

Friendship and peer support are needed for the development of social, emotional and mental health and have been identified as important contributors to a successful school transition (4). Peers not only provide support, but information and guidance (5). However, a peak in bullying victimization occurs following the transition to secondary school (6) largely resulting from the pressure to attain high social status and the formalization of relationships and social roles in new social groups (7). The seriousness and negative impact of school bullying is well known contributing to significant physical, psychological and social wellbeing problems (8) which in turn effects academic performance (9).

In boarding schools, a significantly larger amount of time is spent with peers (24 hours a day, 7 days a week) compared to day students (6 hours a day, 5 days a week). Arguably, the residential boarding context provides greater opportunity for bullying to occur (10, 11).

Some have described bullying at boarding school as 'relentless' given that targets have fewer choices to minimize their exposure to bullying, with bullying often following the target from the day school setting into the residential setting (3). Evidence suggests bullying can become institutionalized into the culture of boarding schools that are not vigilant to its presence (11). Poynting and Donaldson (10) described peer-to-peer bullying in one Australian elite boys' only boarding school as endemic and entrenched, taking the form of ridicule and racial slurs, physical and sexualized assault, all contained within a culture of intimidation and non-disclosure. In these instances bullying has been justified through language that constructs it as a 'tradition' or 'initiation' and analogous with a normal a rite of passage (12).

The long term negative mental health and life trajectory implications for individuals that experience bullying and also perpetrate bullying while at school are increasing being acknowledged (13). Bullying at boarding school has been linked to high levels of shame, anxiety, thoughts of revenge, and experiencing relationship difficulties as adults (3). Despite these apparent harms, a dearth of current information on bullying behaviour in boarding schools exists. This paper uses quantitative data to examine the patterns of bullying behaviours in Australian boarding schools during the initial experience of transition and the year immediately following transition. The primary aim of this study is to determine whether a difference exists in the prevalence and type of bullying behaviours between boarding and non-boarding students and examines help seeking behaviours of those who have been bullied.

METHODS

The data in this study were taken from a larger longitudinal study, the Supportive Schools Project (SSP) conducted in Perth, Western Australia (WA). SSP aimed to develop and implement whole-of-school strategies to reduce the prevalence of frequent bullying behaviours as well as positively influence common mediators of bullying. The study was approved by the ethics committee of the administering institution and the relevant Catholic Education school authorities.

Cohort data were collected during the Supportive Schools Project (SSP) from 3,462 students from 21 of the 28 Catholic secondary schools in WA. The seven schools that declined to participate in the study cited other priorities within their school and demanding staff workloads. All invited CEO schools were stratified according to the total number of students enrolled at the school and each school's Socio-Economic Status (SES) to help to control for the influence of these two factors on student bullying behaviour. These schools were randomly selected and randomly assigned to an intervention or comparison group. To collect data relating to their pre-transition experience, all Grade 7 students enrolled to commence in Grade 8 at each of the 21 participating secondary schools received a baseline survey while in Grade 7 at their respective primary schools. A combination of active and passive consent resulted in 93% of parents whose children were enrolled in the 21 recruited secondary schools consenting to their child participating in the study.

The student cohort was surveyed at the end of Grade 7 (mean age 12 years), the beginning and end of Grade 8 (mean age 13 years old) and the end of Grade 9 (mean age 14 years old). In total, 3,462 (92% of the total recruited) students completed questionnaires at least at one time point with 3,123 (90%) responding to at least three of the four data collection points. One half of the students surveyed were male and 70% attended a co-educational secondary school versus a single sex secondary school. A total of 5% of students (76 males, 74 females) identified themselves as living away from home to complete their secondary education at the secondary schools involved in the SSP.

Measures

Boarder Status. Students in Grades 8 and 9 were asked whether they were living away from home while going to school this year. Those who indicated they were living away from home in Grade 8 have been classified as 'boarders'.

Bullying victimization and perpetration. A global measure of victimization was obtained by asking students 'In the previous term, how often did another student or group of students bully you?' with the response options recorded on a 5 point scale (1=never, 2=only once or twice, 3=every few weeks, 4=about once a week, 5=most days). Similarly a global measure of perpetration was obtained. The type of bullying victimization was assessed using a nine-item categorical index adapted from Rigby and Slee (14), Olweus (15) and from the 2004 Youth Internet Survey (16). Students were asked how often they were bullied through physical (hit, kicked and pushed around; had money or other things broken or taken away from them; made to feel afraid they would get hurt), verbal (made fun of and teased in a hurtful way; called mean and hurtful names), relational (students ignored them, did not let them join in, or left them out on purpose; and students told lies about them and tried to make other students not like them) or cyber (were sent mean and hurtful text (SMS) messages; were sent mean and hurtful messages on the internet) means during the prior term at school. For each item students were asked how often they were bullied, rating each item on a 5 point scale (1 = never, 2 = only once or twice, 3 = every few weeks, 4 = about once a week, 5 = most days). Frequent victimization was defined as every few weeks or more often. The type of perpetration was assessed using a similar nine-item perpetration index which asked students how often they were bullied by others in the different ways listed.

Students were also asked how often they were bullied by other students in various year levels. Those students who reported being bullied were also asked if they asked for help, from whom they asked for help (parents, friends, teachers, school staff) and if things got better after they asked for help.

Bystander behavior was assessed through the question 'If you saw a student being bullied, what did you do?' with the response choices being: I joined in the bullying; I watched the bullying; I walked away; and I tried to get help. Students were also asked whether they: thought the bullying was OK; thought it was none of their business; didn't know what to do; or thought they should help the student being bullied.

Lastly, students were asked how serious they thought staff took bullying: they didn't know; not at all seriously; somewhat seriously; very seriously; or extremely seriously.

Statistical analysis

Analyses were conducted using SPSS v21. Chi-square analyses were used to determine differences in categorical variables with respect to boarders and non-boarders and gender.

RESULTS

At the end of Grade 7, 65% of students reported they were not victimized, 25% reported they were victimized once or twice and 11% reported frequent victimization (every few weeks or more often in the past 10 weeks) (Table 1). The majority of students (71%) reported they did not bully others, 26% reported they bullying others once or twice and 3% reported frequent perpetration (every few weeks or more often in the past 10 weeks).

Boarders vs non-boarders: target of bullying

No significant differences were found for the frequency of bullying victimization between boarders and non-boarders at the end of Grade 7. However, after the transition to secondary school, significant differences were found for the frequency of victimization among students who were boarders and those who were day students only. Boarders reported more frequent victimization at the beginning of Grade 8 ($X^2 = 21.965$, $p < 0.001$), the end of Grade 8 ($X^2 = 17.881$, $p < 0.001$), and the end of Grade 9 ($X^2 = 14.316$, $p = 0.001$) than non-boarders. While the increase in reported frequent victimization over the first two years of secondary school was similar for boarders and non-boarders, by the end of Grade 9 twice as many boarders were frequently victimised than non-boarders, with one in five boarders reporting frequent victimization compared to one in 10 non-boarders by the end of Grade 9.

Table 1. Frequency of victimization and perpetration of boarders and non-boarders

	End of Grade 7		Beg of Grade 8		End of Grade 8		End of Grade 9	
%	Boarder	Non-boarder	Boarder	Non-boarder	Boarder	Non-boarder	Boarder	Non-boarder
Victimization by another student ^{abc}								
Not bullied	61.6	64.7	58.0	71.3	53.3	64.0	49.2	64.7
Once or twice	22.1	24.8	26.6	22.6	26.0	25.9	30.5	24.8
Frequently	16.3	10.5	15.4	6.2	20.7	10.0	20.3	10.5
Perpetration of another student ^{dbc}								
Not bullied	65.1	71.0	77.5	79.9	58.5	74.1	55.2	66.8
Once or twice	33.7	26.0	16.9	17.8	27.5	21.7	30.4	25.6
Frequently	1.2	2.9	5.6	2.3	14.1	4.2	14.4	7.6
Victimization and Perpetration ^{abc}								
Not bullied	53.0	52.9	52.1	63.1	39.4	52.7	34.4	50.4
Once or twice	36.1	40.2	38.6	33.3	44.4	41.3	50.8	41.0
Frequently	10.8	6.9	9.3	3.6	16.2	6.0	14.8	8.5

^a $p < 0.01$ at beg of Grade 8 for boarders vs non-boarders, ^b $p < 0.01$ at end of Grade 8 for boarders vs non-boarders, ^c $p < 0.01$ at end of Grade 9 for boarders vs non-boarders, ^d $p < 0.05$ at beg of Grade 8 for boarders vs non-boarders.

Perpetrator of bullying

Similarly, significant differences were found between boarding and non-boarding students and the frequency of perpetration in which they engaged after their transition to secondary school. Boarders reported engaging in more frequent perpetration of bullying at the beginning of Grade 8 ($X^2 = 6.068$, $p = 0.048$), the end of Grade 8 ($X^2 = 35.243$, $p < 0.001$), and the end of Grade 9 ($X^2 = 10.567$, $p = 0.005$) than non-boarders. By the end of Grade 9, 14% of boarders reported frequent perpetration compared to 8% of non-boarders.

Target/perpetrator of bullying

Similarly, boarders who were victimized and who also perpetrate (bully-victims) also reported they had more frequent involvement in bullying behavior at the beginning of Grade 8 ($X^2 = 15.004$, $p = 0.001$), the end of Grade 8 ($X^2 = 26.427$, $p < 0.001$), and the end of Grade 9 ($X^2 = 13.859$, $p = 0.001$) than non-boarders.

Boarders, gender and bullying behavior

A significantly higher proportion of male boarders reported frequent victimization ($X^2 = 6.908$, $p = 0.032$) at the end of Grade 9 compared to female boarders (27% compared to 14% respectively). A significantly higher proportion of male boarders also reported engaging in frequent perpetration at the beginning of Grade 8 ($X^2 = 13.847$, $p = 0.001$) and end of Grade 9 ($X^2 = 7.576$, $p = 0.023$) compared to female boarders (beginning of Grade 8: 11% compared to

0% respectively; end of Grade 8: 22% compared to 6% respectively). Similarly, a significantly higher proportion of male boarders reported bully-victim behaviours at the beginning of Grade 8 ($X^2 = 6.073$, $p = 0.048$) compared to female boarders (15% compared to 3% respectively).

Type of bullying experienced by boarders

The most frequently reported forms of bullying reported to be experienced by boarders at the beginning of Grade 8 was verbal (being made fun of and teased and called mean names) and relational means (being ignored and excluded and having lies told about them to make students not like them) (Table 2). Physical and cyber bullying became more prevalent at the end of Grades 8 and 9. All forms of bullying increased in prevalence over the first two Grades of secondary school.

With respect to boarders only, no significant differences were found between males and females and the types of victimization they experienced at the end of Grade 7 and the beginning of Grade 8. However, at the end of Grade 8, a significantly higher proportion of males reported verbal bullying than females. Similarly, by the end of Grade 9 a significantly higher proportion of males reported verbal, and physical bullying than females.

A significantly greater proportion of boarding students than non-boarding students reported verbal and relational bullying in both Grades 8 and 9. By the end of Grade 9 a significantly greater proportion of boarding students reported being physically bullied than non-boarding students.

Types of bullying perpetrated by boarders

The most frequent forms of bullying perpetration reported by boarders was verbal and relational bullying (Table 3). Perpetration of physical and cyber bullying became more prevalent at the end of Grades 8 and 9. All forms of bullying perpetration increased in frequency over the first two Grades of secondary school.

At the beginning of Grade 8, a significantly greater proportion of boarding students reported verbally and physically bullying others compared to non-boarding students. This pattern continued to the end of Grades 8 and 9 with a significantly greater proportion of boarding students than non-boarding students reporting verbal, physical, relational, and cyber bullying.

At the beginning of Grade 8, boarders reported being victimized by students in Grades 8, 9 and 10 (Table 4). However, by the end of Grades 8 and 9, boarders predominantly reported being victimized by students in their own grade levels.

Help seeking and bystander behaviour and perceptions of staff

Over one-quarter of boarders who reported being bullied did not ask for help. The majority of boarders in Grades 7 and 8 who witnessed another student being bullied, thought they should help the student being bullied and tried to help. However, by the end of Grade 9, a greater

proportion of boarders who witnessed others being bullied watched the bullying rather than tried to help and thought it was none of their business.

Table 3. Frequency and type of perpetration by boarders from the beginning of Grade 8 to the end of Grade 9

Thought I should help student being bullied	54.7(82)	30.7(46)	18.0(27)

DISCUSSION

This study found significantly higher bullying prevalence rates in boarders after their transition to secondary school. Given, longitudinal research shows that adolescents who are victimised are more likely to experience depression, anxiety, psychosomatic complaints and suicidal ideation (8), and that boarding students are found to have lower levels of mental and emotional wellbeing than non-boarders after the transition to secondary school (17), it seems critically important to prevent and manage these behaviours within the boarding school context.

Unlike non-boarding students whose reported prevalence data was similar to national prevalence data (6), boarders reported significantly higher victimization than the national data and this prevalence increased over time. The increase in prevalence of bullying behaviours following transition and then over time for boarders suggests that their transition to secondary school combined with their transition to boarding school is opportune to skill school staff and students to address bullying behaviours. A case study of an Australian boy's board school (10) found the school minimised and controlled the disclosure of bullying incidents, creating a culture that both tolerated and seemingly admired students who bullied. Students from this boarding school claimed the older students victimised those younger, creating a tradition of bullying within the school. The identification of indecent assaults, sexualised bullying and violence at this boarding school resulted in many Australian private boarding schools reviewing their duty of care and residential supervision practices and procedures (18). Likewise, in response, the Australian Boarding Schools Association (ABSA), which has over 95% of Australian boarding schools as members, developed a Duty of Care: A Certificate Course in Residential Education (19) which set minimal industry based standards (National Boarding Standards (NBS)) in professional training for staff at boarding schools. These standards enable students to be more socially responsible by encouraging pro-social behaviour, discouraging poor behaviour, providing effective anti-bullying policies, and encouraging responsible use of technology (20). While these standards and others developed since are important, a sustainable ongoing strategy of review by schools and governing bodies to prevent and manage bullying is required.

Boarding students in this study perpetrated more bullying than day students. Boarding school practices and policies need to clearly define what social behaviours it expects students

to engage in and what constitutes bullying behaviour and relay this information to all staff and students. Boarding school policies developed in conjunction with boarding students which discourage bullying behaviours, and identify consequences for bullying, need to be administered consistently. Negative outcome expectancies, including adults finding out and adult and peer disapproval, are strong motivational forces to prevent involvement in bullying behaviours (21). Students are less likely to engage in aggressive behaviours if they perceive there will be negative consequences (22). Less than a half of the boarding students in this study believed staff took bullying seriously, with a large proportion of boarders who were victimised not seeking help. Encouraging and enhancing the ability of adults to prevent, detect and intervene in bullying incidents, enabling students to support victimised students, and easy reporting of bullying, will help to reduce victimization (23).

This study showed that boarders who witnessed bullying in Grade 8 thought they should try to help, with this attitude decreasing over time. Participation in perpetration can also be discouraged through encouraging a pro-victim attitude (including support for the victim, empathy towards the victim and disapproval of bullying behaviours) (24). To increase pro-victim behaviour, supporters (those who comfort, support or stand up for those being victimized) need to be acknowledged as positive models for the peer group (25) with students encouraged to perceive all cases of bullying as severe and unjust.

Given, that students in this study were surveyed at the end of Term 1 (10 weeks into the school year) in Grade 8 and again in Term 4 of Grade 8, this six month period resulted in large increases in the prevalence of bullying behaviors for boarders. These changes may be related to changes in boarder attitudes towards bullying due to inconsistent enforcement or lack of bullying policies and procedures. Transition activities and organizational support by boarding schools tend to taper off after the first 10 weeks of the school year as students' are encouraged to take greater responsibility and to self-manage.

The findings from this study suggest it may be necessary to provide mores sustained social support to boarders for the duration of Grade 8. This appears to be a critical time in particular to implement social development programs, clarify boarding house policies and procedures, consistently administer rules, and encourage help seeking behaviours. Preventative steps such as pre-transition seminars and forums for prospective families for new boarding students which outline bullying policies and procedures are also encouraged. The large difference in bullying prevalence between boarders and non-boarders, suggests further research is necessary to explore student socialization processes and staff practices in the residential context and the impact these have on boarding students social and emotional wellbeing and mental health during transition.

Strengths and limitations

There are several strengths of this study. The longitudinal nature of the quantitative research design over the transition from primary into secondary school enabled the investigation of bullying at a time that can be challenging for boarders and non-boarders alike. Moreover, these findings are robust due to the large proportion of boarders (89%) and non-boarders (90%) who completed questionnaires in at least three of the four data collection points.

The limitations of this study include relying on student self-report of bullying victimization and perpetration. The quantitative research was conducted with a sample of Catholic secondary

schools within the Perth metropolitan area which affects the generalizability of results, given they represent only 11% of all secondary schools ($n = 186$) in Perth, Western Australia. School activities over the transition period will likely influence students' experiences. Students were classified as 'boarders' in this study if they indicated they were living away from home while going to school.

These results, however, draw attention to the prevalence of bullying behaviour in boarder populations and suggest opportunities to intercede in the post transition period.

ACKNOWLEDGMENTS

We thank Melanie Epstein, Erin Erceg, and Stacey Waters for their contributions to the Supportive Schools Project (SSP) project, and the SSP study schools and their staff, parents, and students. The SSP Project and this study were funded by the Western Australian Health Promotion Foundation (Healthway) and the research supported by the Child Health Promotion Research Centre (CHPRC) at Edith Cowan University, Western Australia.

Tel Aviv University, Tel Aviv, Israel

ABSTRACT

Data on bullying/cyberbullying and depression/suicide ideation among youth is usually collected via paper-and-pencil questionnaires delivered in classrooms. In recent years data collection methods for psychological questionnaires have seemingly shifted from the classical paper-and-pencil method to web-based questionnaires. There are numerous advantages to web-based methods; however, the exact circumstances in which this method affects data quality are not yet fully understood. Objective: This study will address the question of whether the medium by which data is collected affects results, specifically concerning bullying, cyberbullying, depression and suicide ideation among adolescents. Study group: A total of 230 students participated in the study. Half (n = 115) were recruited online and completed a web-based survey. The other half (n=115) were recruited from five different middle schools and high schools across Israel and completed a paper-and-pencil survey. The participants who completed the paper-and-pencil survey were matched to the online participants in terms of their age, gender and parental occupation status. Methods: Data from both samples were compared and significant differences were further investigated. Results: General cyber-victimization was more prevalent among participants who answered paper-and-pencil questionnaires. Being harassed in virtual chat rooms and suffering from rumors being spread online were the specific types of cyber-victimization that were more prevalent on paper-and-pencil questionnaires. Depression and harassment via e-mail were more prevalent among online

* Corresponding Author's Email: yonatan.shpiegel@gmail.com.

participants. Conclusions: Recruiting participants online has many advantages but it is important to understand the limitations of this sampling method, especially the extent to which it is possible to generalize findings.

Keywords: Web-based research, suicide ideation, bullying, cyberbullying, depression

INTRODUCTION

Bullying, cyberbullying, depression and suicide ideation are major concerns regarding adolescents, particularly given that suicide is the third leading cause of death among American adolescents (1). Moreover, depression and suicide ideation are risk factors for suicide completion (1) as studies show that roughly 1 out of 8 adolescents suffered from depression (2) and 15.8% of high school students seriously considered attempting suicide (3).

In a nationwide survey conducted in 2011, 20% of high school students reported being bullied and 16% reported being cyberbullied during the past 12 months (4). Most of the data for the research on bullying/cyberbullying and depression/suicide ideation among youth has been collected using classical paper-and-pencil self-report questionnaires. This method is expensive, complicated and time consuming; and therefore researchers are turning to more cost-effective alternatives (5). With the growing ubiquity of Internet access (6), an increasing number of researchers are finding ways to utilize the Internet in order to conduct research in their fields. Research on bullying/cyberbullying and depression/suicide ideation is no exception. Recent studies in this field have started collecting data using web-based questionnaires (7, 8). In order to safely advance from paper-and-pencil to web-based research in this field, it is important to systematically compare the two.

The advantages of conducting web-based research are plentiful. Firstly, it provides access to larger and more diverse samples. In addition, data entry in web-based research is done indirectly by participants themselves (9). Lastly, it has been said to provide a heightened sense of anonymity (10) which is considered advantageous, as it encourages honesty when touching sensitive topics (11). However, this heightened sense of anonymity is becoming increasingly harder to assume. People are becoming more knowledgeable about the potential for infringing on anonymity in cyberspace. Therefore, this may theoretically interfere in truthful self-reporting.

The great advantages and promise that web-based research brings does not come without a price. Samples are still confined to participants who own a computer and have Internet access (12). In addition, recruitment techniques, such as advertising in blogs, forums, or web-sites, make it very difficult to achieve a random sample (13). Furthermore, participants are not in a controlled environment during the experiment, it is impossible to verify demographic information, it is difficult to estimate response rates, and finally, with no experimenter watching over participants, ethical problems may arise (13).

Many studies have compared data that were obtained online against data obtained in the lab and have mostly supported the notion that the quality of data (e.g., sample diverseness, responders seriousness, etc.), obtained online is as good as, if not better, than data obtained in the lab (14). Studies comparing data collected using web-based questionnaires and paper-and-pencil questionnaires on potentially sensitive personal matters drew the same conclusion (15). Computer based surveys may be preferable when targeting sensitive issues as the sense of

anonymity increases and social desirability (i.e., a tendency to answer questionnaires in a socially acceptable or favorably viewed way) decreases (15,16). Furthermore, web-based questionnaires have been shown to reliably detect depressive disorders (17) and other mental disorders (18).

Comparing data collection methods among adolescents is necessary for several reasons. First, the popularity of web-based research among adolescents is rising as conducting paper-based research consumes important school time which is also very hard to obtain. Second, adolescents are growing up surrounded by web-based interfaces and spend more time in front of screens, now more than ever (19). For adolescents, answering web-based questionnaires might be becoming more natural than the paper-based alternative.

To the best of our knowledge, most studies have not been conducted among adolescents and while some compared data on the topic of bullying, none have used an online self-selected sample nor have compared differences for cyberbullying. The purpose of the current study is to compare web-based questionnaire and paper-and-pencil questionnaire data collection techniques in relation to researching the sensitive issues of adolescent bullying, cyberbullying, depression and suicide ideation.

METHODS

A total of 230 Israeli middle school and high school students participated in the study. Half of the students ($n = 115$) completed a web-based survey online and the other half completed a paper-based survey. The paper-based survey completers were matched to the online participants in the terms of their age, gender and parental occupation status. In this regard, the participants in both groups ranged in age from 14-17 years of age ($M = 16.06$, $SD = 1$); 122 were male (53%) and 108 were female (47%); 22 were in 9th grade, 42 were in 10th grade, 66 were on 11th grade and 100 were in 12th grade. Out of 230 participants, 198 (86.1%) reported that both of their parents were working.

Procedure

This study was approved by the institutional review board of the Interdisciplinary Center Herzliya. Online participants were recruited via midgam.com, an Israeli web-based survey platform. When signing up to midgam.com, under-aged participants must obtain their parents signature in order to complete their registration. Before answering the questionnaires, all participants signed an online informed consent form. Subsequently, participants were requested to complete the questionnaire in one session and were also informed that the website allows only one entry per participant. All participants were reimbursed 20 NIS (around 6 USD) for their participation in the study.

A paper-and-pencil survey was conducted in 5 middle schools and high schools across Israel as part of a research on the same topic (20). After obtaining approval from a) the Chief Scientist of Israel's Ministry of Education and b) the school principals, all of the participants' parents were contacted via mail and e-mail. Parents were notified about the study and were asked to sign a form if they did not want their child to participate in the study. Students were

asked for their consent in class. Of the 757 participants who completed the questionnaire, 115 were selected to statistically match the online participants in age, sex and parental occupation status.

Measures

Anonymous self-report questionnaires were used to assess participants' experience of bullying, cyberbullying, depression and suicide ideation.

The demographic questionnaire obtained information regarding age, gender and parental occupation status.

Bullying and cyberbullying behavior was assessed using a questionnaire which was previously used by Sourander and colleagues (21). Participants were asked about their involvement in bullying behavior during the past six months, both as a bully and as a victim. The four answer options were 1- never; 2- less than once a week; 3- more than once a week; and 4- almost every day. Participants were regarded as bullies if they reported bullying others during the past six months, either in or out of school, to any extent (i.e., any answer other than "never"). If participants reported being bullied by others during the past six months, in or out of school, they were regarded as victims. Similarly, participants were regarded as cyberbullies or cyber-victims if during the past six months they cyberbullied others or were cyberbullied by others, respectively. In addition to bullying and cyberbullying in general, more specific questions were asked concerning explicit acts of traditional bullying (e.g., hitting, name calling, stealing money, etc.) and cyberbullying (e.g., threatening, rumor spreading, ridiculing, etc.).

Depression was assessed using the Mood and Feelings Questionnaire (MFQ). This self-report questionnaire examines recent depressive symptoms. Participants are asked to mark how true 33 different statements are in accordance with how they have been feeling over the past two weeks (22). Participants can regard each statement either as 0- not true; 1- sometimes; or 2- true. MFQ scores may range between 0-66; this score positively correlates with the prevalence of depressive symptoms. The optimal cut-off point for depressive disorders has been established as 26 or more (23). This point was used to dichotomously differentiate participants as either depressive or non-depressive.

Suicide ideation. In assessing whether a participant had suicidal ideation, any answer other than "Not True" on items 16-18 of the MFQ was taken as indicating passive suicidal ideation. These items included the statements "I thought that life wasn't worth living", "I thought about death or dying" and "I thought my family would be better off without me". Any answer other than "Not True" on item 19 of the MFQ, which held the statement "I thought about killing myself" was regarded as having active suicidal thoughts.

Analysis

To evaluate whether data collected online was significantly different from data collected via paper-and-pencil questionnaires, a series of χ^2 tests for independence was conducted. The tests compared the prevalence of bullying behavior, victimization, cyberbullying, cyber-victimization, depression, passive suicide ideation and active suicide ideation, between the

online and pen-and-paper participants. To better understand the difference between the samples in cyber victimization, an additional series of χ^2 tests for independence was conducted.

RESULTS

Table 1 presents the differences between the online sample and the paper-and-pencil sample regarding prevalence of different behaviors. Bullying, victimization, cyberbullying, passive suicide ideation and active suicide ideation were not significantly different. However, cyber-victimization and depression did significantly differ.

Table 1. Prevalence of behavior among participants in both surveys

Type of Behavior	Online Participants	Paper-and-pencil Participants	Sig of χ^2
Bullying	N=110; 18 (16%)	N=114; 23 (20%)	.286
Victimization	N=110; 24 (21%)	N=114; 36 (31%)	.067
Cyberbullying	N=107; 3 (3%)	N=115; 9 (8%)	.086
Cyber-victimization	N=107; 9 (8%)	N=114; 23 (21%)	.01
Depression	N=115; 21(18%)	N=115; 11(10%)	.043
Passive suicide ideation	N=106; 29 (27%)	N=114; 28 (25%)	.375
Active suicide ideation	N=106; 10 (9%)	N=114; 8(7%)	.342

Table 2. Prevalence of different types of cyber-victimization among participants in both surveys

Type of Behavior	Online Participants	Paper-and-pencil Participants	Sig of χ^2
Ignored by others	N=107; 15 (14%)	N=115; 19 (17%)	.371
Disrespected by others	N=107; 14 (13%)	N=114; 18 (16%)	.353
Called names by others	N=102; 9 (9%)	N=103; 7 (7%)	.39
Had rumors spread by others	N=107; 10 (9%)	N=115; 21 (18%)	.042
Threatened by others	N=107; 4 (4%)	N=114; 5 (4%)	.54
E-mail bombed by others	N=107; 6 (6%)	N=115; 7 (6%)	.554
Picked on by others	N=107; 5 (5%)	N=115; 9 (8%)	.246
Ridiculed	N=107; 12 (11%)	N=115; 19 (17%)	.172
Scared for safety	N=115; 7 (6%)	N=115; 5 (4%)	.384
Virtual chat room	N=107; 12 (11%)	N=115; 24 (21%)	.038
Instant messaging service	N=107; 6 (6%)	N=115; 7 (6%)	.554
E-mail	N=107; 5 (5%)	N=115; 0 (0%)	.025
Phone text messaging	N=104; 2 (2%)	N=115; 0 (0%)	.224
Discussion group	N=107; 7 (7%)	N=115; 9 (8%)	.458
Chat room	N=107; 2 (2%)	N=115; 8 (7%)	.064

Table 2 presents the comparison between specific cyber-victimization experiences. Participants who answered paper-and-pencil questionnaires reported suffering from rumors being spread about them online and being cyberbullied in virtual chat rooms more than did

online participants. More online participants, however, reported being cyberbullied via e-mail. All other comparisons were not significantly different.

DISCUSSION

The current preliminary results indicate that the shift in the social sciences to web-based research must proceed with caution. Our results on bullying, victimization, cyberbullying and suicide ideation generally support previous studies (14) by indicating that web-based research is suitable for adolescents, but further analysis is required, specifically for depression and cyber victimization.

The finding that in the online sample more participants reported being depressed could be explained by the sample characteristics. One major disadvantage of web-based research is that currently there is no method to produce a random sample of Internet users (5). It is possible that adolescents who answer Internet questionnaires spend more time than average online. Intense Internet use has been found to correlate with major and minor depressive symptoms across age, gender and household income (24).

The finding that the online sample reported less cyber-victimization, however, is not consistent with studies indicating that intense Internet use is associated with an increased likelihood of suffering from cyber-victimization (25). According to the leverage-saliency theory of survey participation (26), participants tend to avoid surveys on negatively predisposed topics; hence, the finding that cyber-victimization prevailed less among online participants may be due to a biased sample in which cyber-victims were reluctant to participate in the current online survey. A study investigating cyber-victims' coping strategies found that after being cyberbullied, 20% reported staying offline for a period of time (8). This too, may affect the prevalence of cyber-victims in online studies. Other than sample characteristics, the medium by which data was collected may also play a part in explaining the differences. As suggested by a number of studies, web-based data collection methods may influence responses on computing related items (27, 28). For example, Carini et al. (29) found that students' responses to a questionnaire regarding the degree of engagement in their college experience were more favorable on web-based than on paper-and-pencil questionnaires. Notably, the largest effect they found was generated by the computing and information technology scale.

In our analysis of different types of cyber-victimization we found that more participants from the paper-and-pencil group reported that rumors were being spread about them. This may be due to the nature of this specific type of cyberbullying as it does not require an online interaction (in contrary to other types of cyber-victimization). In fact, one does not even have to have an Internet connection in order for rumors to be spread about them.

When asked about the different mediums where cyberbullying took place, the paper-and-pencil survey reported suffering from more cyber-bullying in virtual chat rooms than did online participants. This finding may support the notion that less cyber-victims answering web-based cyberbullying questionnaires. However, we found an opposite result when asked about cyber-victimization via e-mail. It is possible that cyber-victims' coping strategies like avoiding certain web-sites and discussion groups is very different from avoiding e-mail. First, e-mail is personally delivered and in many cases this is done passively and directly to one's smartphone. This is very different than actively logging into different chat rooms or online forums. Second,

e-mail is harder to disconnect from as it is a more integral part of school than other online communication services. Third, the effect of the platform itself (e.g., computer, smartphone or paper-and-pencil) mentioned earlier may not have as strong an effect being that e-mail, especially among adolescents, is becoming primarily a phone application while web-based studies are still mainly answered using computers.

This is a preliminary study and has several limitations. Firstly, the sample is small. Second, only the online participants were reimbursed for their participation. This may call online participants' motives into question. Furthermore, the two samples might differ in their socioeconomic status, even though parental occupation was controlled for. Third, while the pen-and-paper and web-based groups were not identically controlled, this fits with the objective of the study, namely, to test for differences between a controlled and an uncontrolled environment.

Given these limitations, this study has important implications. Despite the growing popularity of web-based research on sensitive matters among adolescents, it is still uncertain to what extent it is possible to completely generalize findings regarding depression and cyberbullying from self-selected participants recruited online.

We encourage future researchers in the field conducting web-based surveys to acknowledge the restraints of this data collection method. In order to maintain a random sample, surveys completers should not be recruited in a self-selected manner. One option is to continue sampling schools and have as many students of a selected school answer web-based questionnaires from home. This technique may provide many of the advantages of web-based research and strengthen ecological validity.

ACKNOWLEDGMENT

We would like to thank Mrs. Meytal Grimland for allowing us to use data collected by her for a study on the same topic.

Chapter 118

BULLYING: PARENTING STYLES IN VICTIMS AND AGGRESSORS

Maite Garaigordobil*

Department of Personality, Evaluation and Psychological Treatment,
Faculty of Psychology, University of the Basque Country,
Donostia-San Sebastián, Spain

ABSTRACT

The goals of the study were to analyze the relationship between being a victim and/or aggressor of face-to-face bullying behavior and the degree of parents' acceptance/coercion, and parental education styles (neglectful, authoritarian, indulgent, authoritative). The sample comprised 3,026 participants aged 12-18 from the Basque Country (northern Spain). Using a descriptive, comparative, and correlational design, we administered two assessment tools to measure bullying and parental education styles. The results confirmed that it is significantly more likely for victims and aggressors to have parents with low levels of acceptance-involvement (affection, dialogue...) and high levels of coercion-imposition (rules, limits, punishment...) towards their children. In addition, it was also significantly more likely for youngsters who had suffered many face-to-face aggressive behaviors in the past year (high scores on victimization) to have mothers who exerted many behaviors of physical and verbal coercion and deprivation, as well as fathers showing few behaviors of dialogue, low levels of affection, high levels of contempt, indifference, physical and verbal coercion, and deprivation. Furthermore, it was also significantly more likely for youngsters who had performed many face-to-face aggressive behaviors in the past year (high scores on aggression) to have mothers and fathers with low levels of affection, high levels of contempt, indifference, physical and verbal coercion, and deprivation. Analyses of variance confirmed that the authoritarian style (low acceptance-involvement, high coercion-imposition) was the most harmful because the children of authoritarian parents had higher scores on the indicators of bullying (victimization and aggression); that is, they had suffered and performed more face-to-face bullying behaviors. The most positive parental educational style was the indulgent one (high acceptance-involvement, low coercion-imposition) because the children of indulgent parents had lower scores on the

* Corresponding Author's Email: maite.garaigordobil@ehu.eus.

indicators of bullying (victimization and aggression); that is, they had suffered and performed fewer face-to-face bullying behaviors in the past year. The discussion focuses on the importance of the family context to reduce violent peer behavior.

Keywords: bullying, parenting styles, adolescence, youth, violence

INTRODUCTION

This study stems from our concern about the current increase of violence (bullying, racism, sexism, etc.) during childhood, adolescence, and youth. In recent years, interest and social concern about violent peer behavior (bullying) has been increasing. Peer violence has extremely negative consequences for all those involved. Although the most pronounced effects are observed in the victim (anxiety, depression, posttraumatic stress, etc.), aggressors and observers are also the recipients of learnings and negative habits that will affect their current and future behavior. Therefore, studies of the risk and protective factors of bullying are much needed. Within these factors, the variables associated with the family environment hold a relevant position. From a very early age, parents constitute the main means of socialization and development of all individuals. The family is the main socializing agent and, for this reason, it has received much attention from researchers who have explored the influence of variables such as family structure, cohesion, the presence of conflicts, parenting styles, etc. in children's psychological, social, and emotional adjustment.

The parents—relevant socialization agents—represent the culture, and they explicitly or implicitly transmit their social values to their offspring. The family context has considerable influence on the development of social behavior, and there is much empirical evidence confirming that parents who: (1) provide secure attachment; (2) strongly insist that their children should not harm others; (3) make them repair the harm caused when they have hurt and/or attacked others; (4) are altruistic models in their relations with others; (5) reinforce their children's spontaneous acts of sharing, helping, or cooperating through social approval; and (6) adopt a style of inductive discipline within which they discuss their rules—all this increases the probability of the emergence of prosocial behavior in the children (for a review, see Garaigordobil, 2008). Therefore, the family may be the key aspect as a protective and/or a risk factor for the onset of violent behavior. In the family setting, two main parameters of parental behavior conform this influence: (1) the level of affection and communication, and (2) the level of control and discipline.

Bullying is a specific form of school violence, where one or more aggressors intentionally cause pain, harass, and repeatedly submit another classmate. When we talk about bullying, we refer to the existence of a helpless victim, harassed by one or more classmates who perform various types of face-to-face aggressive behavior against the victim (aggressive physical, verbal, social, and psychological behaviors); we refer to sustained physical and mental violence, in which the aggressors have the intention of harming, they behave cruelly and make the victim suffer; there is usually an imbalance of power between victim and aggressors, and the aggressive behaviors are repeated frequently (we do not refer to a punctual aggression); there is a relationship of dominance-submission that is maintained over time (Garaigordobil & Oñederra, 2010).

Olweus (1993), one of the authors of reference in the study of bullying, also found several factors in the family setting that could lead to developing aggressive behavior in children, specifically four factors: (1) Parent's negative attitude along with a lack of affection and dedication would increase the risk of aggressive behaviors, whereas the opposite would act as a protective factor; (2) Parent's lack of clarity when setting limits and rules could, along with the first factor, favor a model of aggressive reaction; (3) If children's caregivers use physical punishment or emotional abuse as a method of affirming their authority, they are promoting these same attitudes in the children; and (4) More impetuous, active, or impulsive children tend to have more aggressive relations with others due to their temperament.

Protective Family Factors against Violence: Communication, Love, Support, Parental Involvement ...

Parental competence is the parents' practical ability to care for, protect, and educate their children, as well as their skills to fulfill their children's needs adequately and appropriately to ensure them a sufficiently healthy development. Various studies have shown that some competent parental behaviors (communication, affection, support, involvement...) stimulate positive development and help to prevent maladaptive behaviors and to protect against bullying.

A positive relationship with the parents, based on the positive expression of feelings (Estévez, Murgui, Musitu, & Moreno, 2008), communication (Georgiou & Stavrinides, 2013; Samper-García, Mestre-Escrivá, Malonda, & Mesurado, 2015) and parental involvement in the lives of the children (Abdirahman, Fleming, & Jacobsen, 2013) are protective factors against victimization.

Low parental support (Cassidy, 2009; Wang, Iannotti, & Nansel, 2009) and the perception of the parents as being distant (Accordino & Accordino, 2011) were related to being a victim of bullying. Various studies have found a relationship between being a victim of bullying and low parental support and family conflict (Dehue, Bolman, Vollink, & Pouwelse, 2012; Fanti, Demetriou, & Hawa, 2012; Khamis, 2015; Low & Espelage, 2013; Wang et al., 2009).

Lack of supervision and conflictive environments have been related to being either a bullying victim or an aggressor (Holt, Kaufman, Kantor, & Finkelhor, 2009), and the lack of affection and dedication and low supervision along with a lack of clear limits and rules increase the risk of the onset of aggressive behavior, whereas the opposite acts as a protective factor (Dehue et al., 2012). Various studies (Garaigordobil, Martínez, & Fernández, 2015; Muris, Meesters, Morren, & Moorman, 2004; Repetti, Taylor, & Seeman, 2002; Steinberg, 2001) have found that low levels of affection and support and a predominance of rejection and aggression towards the children are related to problems of aggressiveness, hostility, and delinquency.

Parental Education Styles: Influence on Victimization and Perpetration of Bullying

Various studies highlight that parents' democratic style, characterized by inductive discipline, positive expression of affection and positive control, plays a decisive role in children's social and behavioral adjustment (Torío, Peña, & Inda, 2008). In the study of Gómez-Ortiz et al. (2015), the democratic supervisor style was the least associated with being a victim

and an aggressor, and the most strongly related to better psychosocial adjustment. In a similar direction, the study of Healy, Sanders, and Iyer (2015) found that the facilitating parental style (warm, democratic, comprehensive, and encouraging independence) was a protective factor against being a victim of bullying. Warm, cohesive homes with clearly established rules were protective factors against perpetrating face-to-face bullying (Morcillo et al., 2015). Complementarily, another study showed that the indulgent style (protective) is associated with the absence of aggressive behavior in the children (Georgiou, 2008).

The literature associating parental styles and anti-social behavior, including bullying, is extensive. Years ago, classical studies such as those of Manning, Heron, and Marshall (1978) or Farrington (1978) pointed out that over-controlled children with dominant and punitive parents harassed their classmates more frequently.

Parental styles characterized by coercive and punitive practices and low affection are related to violence. According to Torío, Peña, and Inda (2008), an authoritarian parental style has negative consequences on socialization because it generates a lack of personal autonomy, less social competence, and low self-esteem.

Authoritarian styles are related to aggression, whereas balanced styles are a protective factor (Baldry & Farrington, 2000, 2005; Georgiou, 2008; Gómez-Ortiz, Del Rey, Romera, & Ortega, 2015; Morcillo et al., 2015). Studies on bullying underline that aggressors perceive less support from their parents, and victims have authoritarian parents (Bibou-Nakou, Tsiantis, Assimopoulos, & Chatzilambou, 2013). Other studies find correlations between the authoritarian style and victimization and perpetration of bullying (Georgiou, Fousiani, Michaelides, & Stavrinides, 2013), and that aggressors have authoritarian (punitive) parents and little parental support (Baldry & Farrington, 2000).

Children raised under authoritarian and neglectful styles are more likely to be victims than those whose parents use authoritative (high acceptance-involvement and high coercion-discipline) and permissive (low involvement and few limits) styles, whereas aggressors' parents use permissive and neglectful styles (Dehue et al., 2012). The perception of an authoritarian parental style is associated with expressions of aggressiveness against peers (De la Torre-Cruz, García-Linares, & Casanova-Arias, 2014) and is a risk factor for perpetration of face-to-face bullying (Morcillo et al., 2015). The permissive style predicts engagement in bullying (Atik & Guneri, 2013) and is associated with aggression throughout childhood development (Ehrenreich, Beron, Brinkley, & Underwood, 2014).

In general, studies suggest that both the authoritarian and the very permissive parenting styles are risk factors, whereas a democratic style based on affection is a protective factor against bullying. However, in contrast with investigations that have emphasized the relevance of the family education style, the study of Lee and Song (2012) found that personal characteristics are the most reliable indicators to detect victimization, and that negative experiences in the family had no relationship with bullying behavior at school.

OBJECTIVES AND HYPOTHESES

Within this contextualization, the goals of this study were to analyze the relationship between being a victim and/or aggressor of face-to-face bullying behavior and the degree of parents' acceptance/involvement and coercion/imposition, and with parenting styles

(neglectful, authoritarian, indulgent, authoritative). With these goals in mind, and with reference to the findings of prior works, the study proposed two hypotheses.

H1: The parents of victims and aggressors of face-to-face bullying will have a low level of acceptance/involvement in the lives of their children and a high level of coercion/imposition. Moreover, the father's educational behavior (dialogue, affection, contempt, indifference, physical and verbal coercion, deprivation) will have more influence on the likelihood of being a victim of bullying than the mother's behavior.

H2: The authoritarian style (low acceptance/involvement and high coercion/imposition) will be related to high scores in bullying (victimization and aggression), whereas the indulgent style (high acceptance/involvement and low coercion/imposition) will be a protective factor against victimization and aggression.

METHOD

Participants

The sample comprised 3,026 participants from the Basque Country (northern Spain), aged between 12 and 18 years, 1,469 (48.5%) males and 1,557 (51.5%) females. The participants studied Compulsory Secondary Education (75.4%) and High School (24.6%), and were enrolled in various public (45.6%) and private (54.4%) schools of the Basque Country. The distribution of the sample by sex and age is presented in Table 1. To obtain the representative sample of the Basque Country, the latest population survey presented by the Basque Statistical Institute was consulted, confirming a population of students of Compulsory Secondary Education and High School of 101,757.

With a .99% confidence level, a sample error of .024, for a population variance of .50, the representative sample comprises 2,802 students. To select a representative sample of students from the Basque Country, we used a stratified, proportional, and randomized sampling technique, taking into account the proportionality of the schools in each province and balancing the diverse conditions (socio-economic-cultural level, type of network: public-private, urban-rural, secular-religious...).

Table 1. Description of the sample: frequency and percentage of males and females in the three age groups

	12-13 years n (%)	14-15 years n (%)	16-18 years n (%)	Total n (%)
Males	543 (51.2%)	536 (49%)	390 (44.8%)	1,469 (48.5%)
Females	518 (48.8%)	558 (51%)	481 (55.2%)	1,557 (51.5%)
Total	1,061 (100%)	1,094 (100%)	871 (100%)	3,026 (100%)

Measures

With the aim of measuring the dependent variables, we applied two assessment instruments with adequate psychometric guarantees of reliability and validity

Bullying was measured with *Cyberbullying. Screening of peer harassment* [in Spanish, *Cyberbullying. Screening de Acoso entre Iguales*] (Garaigordobil, 2013). This is a standardized instrument to assess bullying and cyberbullying behavior. The Bullying Scale assesses four types of presential bullying (physical, verbal, social and psychological aggression) and has 12 items, grouped according to the role performed by the person being evaluated in the aggression situation: victim, aggressor, and observer. The Cyberbullying Scale explores 15 cybernetic-related behaviors (e.g., sending offensive/insulting messages by mobile/Internet, recording a beating and uploading the video to YouTube, sexual harassment, spreading rumors to discredit someone, stealing someone's password, isolating someone on social networks, death threats...). It has 45 items, grouped according to the role performed in the aggression situation: victim, perpetrator, and observer. The test requires participants to read the descriptions of the behaviors and report the frequency with which they were suffered, performed, or observed during the past year. Each behavior is scored as 0 (never), 1 (sometimes), 2 (fairly often), or 3 (always). The test provides percentile scores of four indicators (levels of victimization, perpetration, observation, aggressive-victimization) of "face-to-face" bullying and cyberbullying behaviors, respectively. In both scales, the fourth indicator is obtained by adding score in victimization and in perpetration. Psychometric studies have confirmed its validity and reliability. The Cronbach alpha coefficient obtained by the Bullying scale (12 items) was adequate ($\alpha = .81$), in the same direction as those obtained in its three factors: Victimization ($\alpha = .70$), Perpetration ($\alpha = .71$) and Observation ($\alpha = .80$). In the scale of Cyberbullying (45 items), the Cronbach alpha coefficients were high ($\alpha = .91$), as in its three factors: Cybervictimization ($\alpha = .82$), Cyberperpetration ($\alpha = .91$), and Cyberobservation ($\alpha = .87$). Factor analysis confirmed a 3-factor structure (victims, aggressors, observers in the Bullying and Cyberbullying Scales that explain, respectively, 57.89% and 40.15% of the variance). Studies of convergent validity showed positive correlations ($r = .58$) between the level of victimization in situations of high face-to-face bullying as measured with the Cyberbullying Test and with the AVE (Piñuel & Oñate, 2006).

Parenting styles were measured with *Parental Socialization Scale for Adolescence* [in Spanish, *Escala de Socialización Parental en la Adolescencia*] (ESPA-29. Musitu & García, 2001). This scale assesses the parents' socialization styles, that is, the parenting styles of the father and mother towards their children. The adolescent rates the father's and mother's action independently in 29 relevant situations. Of the 29 situations proposed, 16 are negative ("If I am dirty and poorly dressed," "If one of my teachers tells him/her that I behave badly in class," "If I am disobedient"), and 13 are positive ("If I take care of my things and am clean and properly dressed," "If I do not skip classes and arrive punctually every day," "If I pick up and take care of things at home"). The respondent reports the way his or her parents act when the situations described in the questionnaire occur. The questionnaire allows identifying 4 parenting styles of the father and mother along the acceptance/involvement - coercion/imposition continuum: authoritative, indulgent, authoritarian, and neglectful. *Authoritative parents* (high acceptance/involvement and high coercion/imposition): They make an effort to guide the activities of their son/daughter rationally, sharing the rationale underlying their policy, they affirm their children's qualities, but they also set limits and the course of future behavior, resorting both to reasoning and to power to achieve their goals. *Indulgent parents* (high acceptance/involvement and low coercion/imposition): They attempt to behave affectionately, they accept their children's impulses, desires, and actions, and allow them to regulate their own activities as much as possible, they offer explanations and rationale, but they avoid the use of

dominant or coercive control. *Authoritarian parents* (low acceptance/involvement and high coercion/imposition): They frequently do not offer any rationale when they give orders and are very reluctant to modify their positions in the face of their children's arguments. They are generally indifferent to their children's demands for support and attention and they are less likely to use positive reinforcement, acting indifferently towards their children's appropriate behaviors. *Neglectful parents* (low acceptance/ involvement and low coercion/imposition): They have severe difficulties to relate to and interact with their children, and to set limits for them, and they express little affection. Psychometric studies of the scale reveal high internal consistency. The results of factor analysis confirmed the theoretical structure of the bidimensional model satisfactorily. In the present study, the internal consistency coefficients were high (mother $\alpha = .91$, father $\alpha = .93$).

Design and Procedure

We used a descriptive, comparative, correlational, and cross-sectional design. With regard to the procedure, the following phases were established: (1) A letter was sent to the directors of the randomly selected schools from the list of educational centers in Basque Country, explaining the project and requesting their collaboration; (2) Communication with the directors: we performed an interview with those who agreed to collaborate in order to present the project and hand out the informed consent forms for the parents of the participants in the study; if the director of the selected center refused to collaborate, the procedure was repeated with the next center on the list, taking into account the type (public-private) and/or the socio-economic-cultural level of the center that declined to participate; and (3) After receiving the parents' consent, the research team (Psychology graduates and Ph.D. students) administered two assessment instruments. The administration was carried out in one 60-minute assessment session. The study respected the ethical values required in research with humans (informed consent and the right to the information, protection of personal data and guarantees of confidentiality, non-discrimination, gratuity, and the possibility to leave the study at any phase), and received the favorable report of the University Research and Teaching Ethics Committee of the University of the Basque Country (CEISH/112/2012).

RESULTS

Degree of Parental Acceptance/Involvement and Coercion/Imposition in Victims and Aggressors of Bullying

In order to explore the level of acceptance/involvement and coercion/imposition of the fathers and mothers of victims of bullying, first we divided the sample into two groups, those who had suffered one or more aggressive behaviors in the past year (1,182) and those who had not suffered any aggression (1,844). Subsequently, an analysis of variance was conducted to compare the level of acceptance/involvement and coercion/imposition of the fathers and mothers in both subsamples, also calculating the effect size (Cohen's d). The results (see Table 2) showed that significantly the participants who had experienced one or more face-to-face

aggressive behaviors in the past year (occasional and severe victims) had fathers and mothers expressing few behaviors of acceptance/involvement in their children's lives and also with many behaviors of coercion/imposition (much discipline, rules, limits, punishments...) towards them. However, the effect size was small.

Table 2. Victims: level of parents' acceptance/involvement and coercion/imposition

	Non-victim (n = 1.844)	Victim (n = 1.182)	F (1, 3024)	d
	M (SD)	M (SD)		
Mother's acceptance/involvement	3.29 (0.41)	3.24 (0.41)	5.69 *	.12
Mother's coercion/imposition	1.72 (0.39)	1.79 (0.36)	12.03 ***	-.18
Father's acceptance/involvement	3.20 (0.49)	3.10 (0.53)	14.66 ***	.19
Father's coercion/imposition	1.71 (0.43)	1.79 (0.44)	14.81 ***	-.18

Regarding the aggressors, the same procedure was carried out: we divided the sample into two groups, those who had performed one or more aggressive behaviors in the past year (1,157) and those who had not attacked anyone (1,869), and we conducted an analysis of variance, the results of which are presented in Table 3. Similar results were found, as can be observed. The data confirmed that significantly those who had performed one or more face-to-face aggressive behaviors in the past year (occasional and severe aggressors) had fathers and mothers expressing few behaviors of acceptance/involvement in their children's lives and also with many behaviors of coercion/imposition towards them (much discipline, rules, limits, punishments...), with a small effect size.

Table 3. Aggressors: level of parents' acceptance/involvement and coercion/imposition

	Non-aggressor (n = 1.869)	Aggressor (n = 1.157)	F (1, 3024)	d
	M (SD)	M (SD)		
Mother's acceptance/involvement	3.30 (0.40)	3.21 (0.42)	18.73 ***	.21
Mother's coercion/imposition	1.72 (0.38)	1.81 (0.37)	20.27 ***	-.23
Father's acceptance/involvement	3.21 (0.49)	3.09 (0.52)	22.95 ***	.23
Father's coercion/imposition	1.71 (0.43)	1.80 (0.44)	17.54 ***	-.20

To examine in more depth the connections between parents' acceptance/involvement and coercion/imposition with victimization and aggression, we calculated partial correlations between victimization and aggression with various specific factors of acceptance/involvement (dialogue, affection) and coercion/imposition (contempt, indifference, physical and verbal coercion, and deprivation), while taking into account sex, age, and socio-economic level. The correlation coefficients obtained are shown in Table 4. The results revealed that: (1) it was significantly more likely for participants who had suffered many face-to-face aggressive behaviors in the past year (high scores on victimization) to have mothers showing many behaviors of physical and verbal coercion and deprivation, as well as fathers with few behaviors of dialogue, low levels of affection, many behaviors of contempt, indifference, physical and verbal coercion, and deprivation; and (2) it was significantly more likely for those who had performed many face-to-face aggressions in the past year (high scores in aggression) to have

mothers and fathers with low levels of affection, many behaviors of contempt, indifference, physical and verbal coercion, and deprivation.

Table 4. Partial correlations between victimization and aggression with parents' behaviors of acceptance/involvement and coercion/imposition

	Mother		Father	
	Victimization	Aggression	Victimization	Aggression
	<i>r</i> (<i>p</i>)	<i>r</i> (<i>p</i>)	<i>r</i> (<i>p</i>)	<i>r</i> (<i>p</i>)
Dialogue	-.03 (.138)	-.01 (.411)	-.06 (.014)	-.04 (.092)
Affection	-.00 (.825)	-.08 (.001)	-.05 (.016)	-.09 (.001)
Contempt	.01 (.595)	.10 (.001)	.06 (.012)	.09 (.001)
Indifference	.04 (.081)	.11 (.001)	.08 (.001)	.12 (.001)

Deprivation	.09 (.001)	.11 (.001)	.12 (.001)	.11 (.001)
Verbal coercion	.07 (.001)	.05 (.011)	.09 (.001)	.06 (.013)

Bullying: Parenting Styles of Victims and Aggressors

After confirming the basic assumptions (normality, homoscedasticity...), in order to analyze the parenting style (neglectful, authoritarian, indulgent, authoritative) of victims and perpetrators of bullying, we performed descriptive (means, standard deviations) and inferential analyses (analysis of variance) with the scores obtained on the two evaluation instruments. In addition, we performed *post hoc* group comparisons (Bonferroni) of the four parenting styles.

Table 5. Means, standard deviations, analysis of variance and *post hoc* (Bonferroni) of the parenting style with indicators of bullying

Mother	Negligent	Authoritarian	Indulgent	Authoritative	<i>F</i> (3,3022)	<i>Post hoc</i>
	<i>M</i> (<i>SD</i>)	<i>M</i> (<i>SD</i>)	<i>M</i> (<i>SD</i>)	<i>M</i> (<i>SD</i>)		
Victimization	0.69 (1.25)	0.88 (1.51)	0.58 (1.18) 0.49 (0.93)	0.83 (1.45)	4.58**	2>3;4>3
Aggression	0.72 (1.29)	1.06 (1.80)		0.76 (1.35)	11.27***	2>1,3,4
Father						
Victimization	0.72 (1.32)	1.11 (1.81)	0.46 (0.93) 0.51 (1.07)	0.77 (1.37)	13.08***	2>1,3,4
Aggression	0.71 (1.31)	0.99 (1.46)		0.69 (1.33)	7.45***	2>1,3,4

Note. * $p < .05$, ** $p < .01$, *** $p < .001$; *Post hoc* = Bonferroni's group comparison.

The analyses of variance confirmed that the authoritarian style (low acceptance/involvement, high coercion/imposition) was the most harmful because the participants whose parents (father and mother) were authoritarian obtained significantly higher scores on the bullying indicators (victimization and aggression); that is, they had suffered and performed more face-to-face bullying behaviors. The most positive parenting style was the indulgent one (high acceptance/involvement, low coercion/imposition) because the participants whose parents (father and mother) were indulgent obtained significantly lower scores on the bullying

indicators (victimization and aggression); that is, they had suffered and performed fewer face-to-face bullying behaviors in the past year. It should also be observed that, after the authoritarian style (low acceptance/involvement and high coercion/imposition), the authoritative style (high acceptance/involvement and high coercion/imposition) was the worst education style, even worse than the neglectful style (low acceptance/involvement and low coercion/imposition).

CONCLUSION

The goals of this study were to analyze the relationship between being a victim and/or perpetrator of face-to-face bullying and the degree of parents' acceptance/involvement and coercion/imposition, and parenting styles (neglectful, authoritarian, indulgent, authoritative).

Firstly, the results have confirmed that adolescents and youth who had suffered and carried out one or more face-to-face aggressive behaviors in the past year (victims and aggressors) had fathers and mothers showing few behaviors of acceptance/involvement in the lives of their children (dialogue, positive expressions of affection...) and many behaviors of coercion/imposition (much discipline, rules, limits, punishment...) towards them. In addition, it was also significantly more likely for youngsters who had suffered many face-to-face aggressive behaviors in the past year (high scores on victimization) to have mothers who exerted many behaviors of physical and verbal coercion and deprivation, as well as fathers showing few behaviors of dialogue, low levels of affection, high levels of contempt, indifference, physical and verbal coercion, and deprivation. Participants who had carried out many face-to-face aggressive behaviors in the past year (high scores on aggression) had mothers and fathers with low levels of affection, many behaviors of contempt, indifference, physical and verbal coercion, and deprivation. Therefore, behaviors related to the parental style of fathers and mothers have a similar influence on the probability of being an aggressor, but the father's behavior has more influence on victimization.

Thus, the results confirm Hypothesis 1, which proposed that victims and aggressors had parents with a low level of acceptance/involvement in the lives of their children and high levels of coercion/imposition. Moreover, the father's behavior (dialogue, affection, contempt, indifference, physical and verbal coercion, deprivation) influenced the likelihood of being a victim of bullying more than the mother's behavior. These results confirm studies that have found that low parental support (Cassidy, 2009; Dehue et al., 2012; Fanti et al., 2012; Khamis, 2015; Low & Espelage, 2013; Wang et al., 2009) and the perception of the parents as being distant (Accordino & Accordino, 2011) are related to being a victim of bullying, and also studies that have identified low parental support in aggressors (Baldry & Farrington, 2000). In addition, we ratify the results of investigations that have shown that the lack of affection, dedication, and low parental supervision increase the risk of the onset of aggressive acts, whereas the opposite acts as a protective factor (Dehue et al., 2012; Muris et al., 2004; Olweus, 1993; Repetti et al., 2002; Steinberg, 2001).

Secondly, the results confirm that adolescents and youth whose parents (father and mother) used an authoritarian education style (low acceptance/involvement, high coercion/imposition) had higher scores on aggression and victimization; that is, they had suffered and carried out significantly more face-to-face bullying behaviors. The most positive parenting style was the

indulgent one (high acceptance/involvement, low coercion/imposition) because the participants whose parents (father and mother) were indulgent had suffered and performed significantly fewer face-to-face bullying behaviors in the past year.

Therefore, the results also confirm Hypothesis 2, which postulated that the authoritarian style would be associated with involvement in bullying situations both as a victim and an aggressor, whereas the indulgent style would be a protective factor against victimization and aggression. In addition, results confirm findings of studies on face-to-face bullying that have found that victims and aggressors had authoritarian parents (Baldry & Farrington, 2000, 2005; Bibou-Nakou et al., 2013; Gómez-Ortíz et al., 2015; Georgiou et al., 2013; Morcillo et al., 2015), whereas the indulgent style (protective) was related to the absence of aggressive behavior in children (Georgiou, 2008; Morcillo et al., 2015).

Two conclusions can be drawn from the results obtained: (1) a high level of acceptance/involvement in the life of the children by both parents (involving high doses of dialogue and affection) is an educational variable that strongly influences the prevention of victimization and the inhibition of aggressive behavior, and it is more important than the degree of parents' coercion/imposition (involving many rules and high levels of discipline and punishment) because the indulgent style (high acceptance/involvement and low coercion/imposition) is associated with low victimization and low levels of aggressive behavior; and (2) the authoritarian education style (low acceptance/involvement and high coercion/imposition) by both parents is the one that most favors engaging in bullying situations, both in the role of victim and in that of aggressor. Parenting styles characterized by coercive and punitive practices and low affection are related to violence. Authoritarian parents often do not give any reasons for their orders and they are very reluctant to change their minds in the face of their children's arguments; they are generally indifferent to the children's demands of support and care, and they are less likely to use positive reinforcement, showing indifference to their children's appropriate behavior. This pattern of parental behavior has been shown to be related to the likelihood of becoming a victim and an aggressor of bullying.

In general, the results obtained point in the same direction as other studies that have emphasized that authoritarian parenting styles are risk factors, whereas a democratic and affection-based style is a protective factor against bullying. The findings of this study emphasize the importance of the family, as opposed to the study of Lee and Song (2012), who concluded that negative experiences in the family have no relationship with bullying behavior at school, granting more explanatory power to personal characteristics. Although it has been proven that some personality traits are more likely in the victims (few social skills, low self-esteem...) or in the aggressors (low empathy, impulsivity, low frustration tolerance...) (Garaigordobil, 2013), both parents' educational behavior towards their children is very important for the development of the children's personalities, ethical values, in their psychosocial adjustment and, therefore, in the probability of being involved in bullying situations.

This study contributes to the identification of family variables that influence bullying and suggests the need to develop programs of family education that lead to changes in parents' way of educating their children, their disciplinary practices, degree of attention, involvement, and affection towards their children. These results suggest the importance of working with parents to promote high acceptance/involvement in the lives of their children, combined with a reasonable level of coercion/imposition, which would result in the prevention of bullying. The indulgent parenting style implies that parents behave affectionately, accepting their children's

impulses, desires, and actions, and allowing them to regulate their own activities as much as possible, giving explanations and reasons for their orders but avoiding negative and coercive control.

However, despite the strong influence of the family in the development of children's ethical-moral values and social behavior, intervention to prevent and reduce bullying must also count on the collaboration of the school because the school context is another very relevant area in the process of socialization. Collaboration between parents and the school is of vital importance for the elimination of bullying. Evidence-based antibullying intervention programs (e.g., Garaigordobil & Martínez-Valderrey, 2014ab, 2015ab, 2016; Olweus 2004, Olweus et al., 2007, Olweus & Limber, 2010ab) should be carried out at school, as well as programs that promote childrens' social and affective-emotional development (i.e., that encourage assertive communication, listening skills, empathy, the prosocial behaviors of helping and cooperation, respect for differences, the ability to resolve conflicts constructively...) because all this will have a significant effect on preventing peer violence.

As a limitation of the study, we note the use of self-reports with the implied bias of social desirability; therefore, for future studies, we recommend administering the assessment instruments concerning their educational practices to the parents, as this would allow contrasting the results obtained in this study. In addition, future studies could explore connections of parental education with bullying, but differentiating pure victims, pure aggressors, and aggressive victims.

ACKNOWLEDGMENTS

The study was financed by the Spanish Ministry of Economics and Competitiveness (MINECO) (PSI2012-30956), by the Department of Education of the Basque Government (IT-638-13), and by the Training and Research Unit of the University of the Basque Country (UFI PSIXXI 11/04).

Chapter 119

HOMOPHOBIC BULLYING: AN OLD PROBLEM ONLY RECENTLY BROUGHT TO LIGHT

ABSTRACT

Bullying is a phenomenon which has been widely studied in our schools in recent years. With the emergence of communication and information technologies, the phenomenon has become more complex, expanding into what is known as cyberbullying. However, in LGBT students these phenomena seem, on the one hand, to be overrepresented and, on the other, show specific characteristics. Thus, while they share some common elements with the original form of bullying, it appears that homophobic bullying and cyberbullying should be considered as phenomena in their own right.

This chapter analyzes the scientific literature on this topic, showing its idiosyncrasy. It starts by addressing the topic of bullying and goes on to show why homophobic bullying should be considered as specific. Social homophobia, as well as the sex-gender norm, are analyzed to gain a more precise understanding of the problem. The chapter then looks at the main data for prevalence across countries and the consequences of these problems on young people. It also includes some specific data about these phenomena in Spain. The chapter ends with conclusions and looks at practical implications.

1. INTRODUCTION

Violence and its manifestations in different contexts constitutes one of the main social problems we are faced with today. The Declaration of Human Rights, a document widely adopted by developed societies, states in Article 5 that “No one shall be subjected to torture or

* Corresponding Author’s Email: mpelipe@ujaen.es.

to cruel, inhuman or degrading treatment or punishment” (UN General Assembly, 1948). Despite this, violence persists in different areas making the understanding of its causes and the design of strategies to eradicate it a fundamental objective for the development of society. For that reason, it is important to analyze specifically each of the phenomenon which give rise to the violence because, even though they may all share the use of violence, the causes and factors which encourage it and, correspondingly, the way to eradicate it, will be different for each type. In this sense, one of the most widely studied violent phenomena in the school setting is bullying and its more recent counterpart, cyberbullying. The study of these phenomena is making it possible to identify more precise details, thus furthering understanding. It is within this area that a specific type of bullying has been identified, homophobic bullying.

Furthermore, affective-sexual diversity is a subject which has only recently been taken into account in a more or less explicit manner in the school setting. However, this diversity has been included implicitly for some years in the respective child protection legislation. Thus, Article 2 of the Convention of the Rights of the Child (UN General Assembly, 1989) includes the fundamental right to non-discrimination. In the same way, Articles 28 and 29 of said declaration, as well as Article 26 of the Universal Declaration of Human Rights, state that the objective of education is the full development of human personality in the respect of human rights and fundamental liberties. Therefore, although this is sometimes proposed as a recent issue, we understand that, as a part of the development of the personality, its inclusion in the school setting is supported and backed up by the above-mentioned legislation.

2. BULLYING AND CYBERBULLYING

Olweus (1999) conceptualized bullying as an intentional aggression perpetrated by a student or group of students repeatedly, and persisting over time, against one or several victims in a relation in which there is an imbalance of power. As has happened with other forms of abuse, while the phenomenon may not be new, the level of awareness and sensitivity that exists towards it certainly is more recent. Since the end of the 1990s, there has been a steady increase in both evaluation measures and intervention proposals to try to eradicate the phenomenon. Likewise, its scientific study has given us a more precise picture of the nature of bullying and the factors associated with it. However, as it is a relational phenomenon, its manifestations have also been changing over time as we have been changing the way we relate to each other. The eruption of information and communication technologies has produced a radical change in peer interaction. In addition to relations where individuals interact physically, people can now interact at a distance without physically being present – and the specific characteristics of this new type of interaction are delimited primarily by the context in which they take place: cyberspace. Negative interpersonal dynamics such as bullying have also moved or, perhaps more accurately, extended to this context, with the rise of what is known as cyberbullying.

Cyberbullying has been defined by Smith et al., (2008), in an extension of Olweus’ definition of traditional bullying, as “an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself” (p. 376). Furthermore, the actual medium in which this takes place confers a series of specific characteristics: the aggression can occur at any time and in any place; it may have an enormous audience and be seen an infinite number of times; and

it can even be anonymous, although in most cases the abuse is carried out by a person known to the victim (Mora-Merchán & Ortega, 2007).

Therefore, both phenomena, bullying and cyberbullying, consist of immoral and harmful relational dynamics which break the reciprocity which should prevail in peer relations.

While any student is a potential victim of these aggressions, it seems that this type of abuse is more likely to occur against those who are perceived as “different” whether this be because of their skin color, cultural background, religious belief, learning or motor impairments or actual or perceived sexual orientation to the rest of their peers (Rivers, 2011). In fact, as we shall explain below, several studies have demonstrated how the prevalence of victimization amongst LGBT students is higher than among the rest of their colleagues. However, when we talk about homophobic bullying we are not just referring to these students.

3. HOMOPHOBIC BULLYING AS A SPECIFIC PHENOMENON

In general terms, homophobic bullying refers to those situations of bullying which are motivated by actual or perceived sexual orientation. However, this definition is reductionist given that, beyond sexual orientation, this bullying occurs when a breach in established gender patterns is perceived.

As Minton, Dahl, O’Moore, and Tuck (2008) state, we find two types of homophobic bullying: heteronormative bullying, in other words, the non-normalization of any aspect which departs from heterosexuality (assuming that all people are heterosexual and referring to them as such); and bullying directed, specifically, at people who are known, or thought, to have a non-heterosexual orientation. Furthermore, as several authors state, this bullying is also aimed at people whose personal characteristics or actions do not reflect socially established gender patterns (Generelo & Pichardo, 2006; Platero, 2008).

There are different reasons which justify the consideration of this type of bullying as a phenomenon which, while it is closely related, has sufficient characteristics of its own to be considered specifically. However, the main cause lies in the “structural” homophobia which exists in society as a whole, and in schools in particular. We shall analyze the latter in the following section.

3.1. Homophobia in the School

Firstly, we need to clarify what we understand by homophobia. The concept refers to a series of negative ideas and emotions towards those behaviors and attitudes which depart from heterosexuality, provoking reactions and discriminatory behaviors ranging from denial to aggression and reaching, in the event of being interiorized by the people involved, self-denial and different negative emotions (Gualdi et al., 2008). Although the term refers to a personal rejection, the reality is that it is “a culturally constructed social prejudice interiorized through socialization” (Pichardo, 2015: 11). This author states that we have all been socialized in sexism and homophobia, in the idea of rejection of homosexuality and people who are, or seem to be, homosexual or bisexual. Hence, these prejudices need to be “unlearned” at a social and individual level. Furthermore, homophobia is not just aimed at people with a non-heterosexual sexual

orientation, it can be directed at any situation, person or behavior which breaches the norms of the sex-gender system. This system establishes a supposedly natural binarism, assigning a series of masculine or feminine features depending on biological sex (boy-masculinity, girl-femininity). Thus, homophobia rejects any behavior perceived as different in this sense: non-heterosexual affective-sexual orientation, manifestations of identity, emotions, behaviors or physical appearance, which do not clearly correspond to the above-mentioned binarism. Here, we would also include the transsexual student, homo-parent families and any other aspect, which departs from what is “heteronormative.”

Thus, it would seem that homophobic attitudes persist in our societies in general. Proof of this is that sexual orientation appears in different countries in the European Union, among them Spain, as one of the main causes of hate crimes (Spanish Ministry of the Interior, 2014, 2015). It has even been linked to such violent phenomena as school shootings in the US (Klein, 2006).

In some schools, an approach towards affective-sexual diversity is conspicuously absent as the family continues to be considered (defended by various associations such as the Foro de la Familia [Family Forum] in Spain) as “that consisting of the matrimonial union between a man and a woman,” thereby emphasizing the reality of “heteronormativity.” In other countries, such as Peru, students propose that the subject of homosexuality should only be dealt with sporadically at school and, when it is covered, there are two contradictory discourses: on the one hand, tolerance is promoted, but on the other, it is suggested that it is something bad (Cáceres & Salazar, 2013). In fact, some studies have shown a greater prevalence of homophobic bullying in religious schools than in secular state schools (Hunt & Jensen, 2007). Romero, Martín, and Castañón concluded in a study in 2006 that minority sexual identities are invisibilized at school, at least in Spain, so that youngsters from these groups feel isolated, rejected and misunderstood. Along the same lines, Kosciw, Greitak, Palmer, and Boesen (2014) showed in their study that more than half of LGBT students stated that they had experienced discriminatory practices or policies associated with their sexual and/or gender orientation in their schools. Furthermore, in both this study and that by Guasp, Statham, Jadva & Daly, (2012), students stated that although the school had been informed and the teachers were aware of this discrimination, they did not intervene to stop it. Some studies, such as that by Rivers (2001), highlight that very few victims of homophobic bullying told their teachers about it (and only 16% told them the reason for the bullying) and over 25% said they had been harassed by a teacher due to their actual or perceived sexual orientation. As a result of this, most thought that it was a risk to tell a teacher about it, particularly in schools where homosexuality was presented as sinful or where teachers either used, or did not penalize, the use of homophobic language in class. In their study of schools in Peru, Guatemala and Chile, Cáceres & Salazar (2013) pointed out that the vulnerability of students perceived as “different” because they did not meet the gender and hetero-normative mandates grew worse as a result of the hidden curriculum. In other words, to different degrees across the countries studied, schools prevented demonstration, silencing and invisibilizing those who were different through homogenization, thereby reinforcing this rejection.

On the other hand, several studies have demonstrated that the construction of masculinity is based on disdain towards what is considered “other, not masculine,” which has important consequences for children’s development. Phoenix, Frosh and Pattman (2003) showed how boys try to show themselves in the school setting as “appropriately masculine” to avoid being victimized or labelled as gay. Similarly, other studies have shown how homophobia is used by boys to defend and reinforce their masculinity, distancing themselves from “the feminine other”

(Nayak & Kehily, 1996; Swain, 2000). As Pichardo (2009) has pointed out, in many societies “being masculine” involves the rejection of homosexuality and LGBT people, so homophobic attitudes among males are more frequent.

This all shapes what Pichardo (2015) has called the homophobia continuum. In other words, homophobia is not just limited to peer relations. Instead we find it in schools, in the street, in groups of friends, associations; in short, in any context. Thus, unlike other types of bullying, the rejection suffered by victims of homophobia is not just limited to peers, thereby making it harder to report the bullying. Hence, this author believes that, as reporting in these cases may mean having to reveal the “reason” for the bullying, the victim will often decide to say nothing. Likewise, witnesses will be more reticent about reporting the bullying or putting themselves on the side of the victim for fear of “stigma contagion”; in other words, for fear of being considered “gay” and themselves becoming the target of abuse. It is important to underline that, although the law of silence was mentioned by Ortega (1998) as a constitutive element of general bullying, in the case of homophobic bullying that concerns us here, this added element of “social stigma” would make it worse.

All these aspects emphasize that while the form and manifestations of this type of bullying share the characteristics of “general” bullying (repeated aggression, with intention to cause harm to a victim who cannot defend him or herself) the actual social and school contexts give it a specificity which deserves to be taken into account.

4. PREVALENCE OF HOMOPHOBIC BULLYING

While there are still relatively few studies quantifying this problem, those that have been conducted have found that aggressions in general, and bullying in particular, are more prevalent among LGBT students than the rest.

A study in the US conducted by the Gay, Lesbian, and Straight Education Network (GLSEN), found that approximately 92% of lesbian, gay, bisexual and transgender students informed that they had heard homophobic comments and 84% said they had been verbally abused (Kosciw, 2004). In Europe, homophobia and transphobia are the main motives for insults, slurs and rejection in schools (British Council, 2010).

As for bullying itself we find, as with studies on general bullying, that results vary across countries and studies, possibly due to differences in the phenomenon itself or to methodological aspects such as the way samples are accessed or how they are conceptualized and/or evaluated. Thus, in studies performed with the general population, the rates show 67% in Mexico (Baruch, 2012); in Peru 68% compared to 43% in heterosexual students (Cáceres & Salazar, 2013); 48% in boys and 17.7% in girls in Norway (Roland & Auestad, 2009); in Ireland 18.2% of boys and 9% of girls. In Spain, a recent study (Elipse, Muñoz, & Del Rey, under review) found nearly double the victims in the non-heterosexual population compared to their heterosexual counterparts (45.4% v. 26.7%) with the major differences occurring in severe victimization, where the victim informed to have suffered the aggression with a frequency of once or twice a week or more, (16.6% in heterosexual students v. 33.3% in non-heterosexual students).

When LGBT students are interviewed, in most studies, more than half state that they have suffered this type of abuse. In the UK, Rivers (2001) found that 82% of gays and lesbians reported insults, mainly of a homophobic nature: 60% reported having been hit or kicked; 58%

had been teased; 59% had rumors spread about them; and 27% had suffered from social isolation. Also in the UK, a more recent study found that 55% of LGB students reported suffering homophobic bullying (Guasp et al., 2012). In Spain, 57.38% of a sample of students self-identified as non-heterosexuals stated that they had been victims (Marchueta, 2014).

As for cybernetic aggressions, the few studies that have been conducted have found a greater prevalence amongst LGBT students. From a sample in which 9% self-identified themselves as non-heterosexual, Hinduja and Patchin (2011) found that 36% of these had been cybervictims compared to 20.1% of the heterosexual students. Blumenfeld and Cooper (2010) found that more than half of the cybervictims in their study (54%) were so because of their sexual orientation. In Spain, our study found, as with traditional bullying, double the number of cybervictims among non-heterosexual students (21.2% v. 11.1% in heterosexuals); in this case, the rate of severe cybervictims was four times higher (4.1% heterosexual students v. 16.7% among non-heterosexual students) (Elipe et al., under review).

Regarding the most frequent type of behaviors, in relation to traditional bullying, in our study, we found the following, in decreasing order: insults, saying nasty things to others about the victim, social exclusion and spreading rumors (Elipe et al., under review). These last two forms were especially frequent among the non-heterosexual students (see Graph 1). These behaviors coincide, to a great extent, with those found in the study by Rivers (2001).

Graph 1. Percentage of students, heterosexual (H) v. non-heterosexual (NH), who reported having suffered each victimization behavior.

These results are in line with previous studies (e.g., Marchueta, 2014; Rivers, 2001) in which verbal aggression, direct insults and humiliation in front of other people, and the spreading of rumors are among the main forms used. It seems to have become normal to insult with words referring to sexual orientation to harm non-heterosexual people. It is also remarkable how both behaviors of indirect (social exclusion), and direct aggression (hitting people, in the most severe form, or threats, in a sporadic form) are triple the number amongst non-heterosexual students. Likewise, the spreading of rumors, both in its sporadic and severe

form, is double in the case of non-heterosexual students. Finally, we should mention the aggression of taking or breaking things, sporadically, which is nine times more likely to happen amongst these students; Rivers (2001) found this aggression in almost half of the victims in that study.

In the case of cybervictimization, as Graph 2 shows, the most frequent behaviors were: to say nasty words to others about the victim using internet or SMS (B); insults using email or SMS (A); sporadic threats using internet or SMS (C) spreading of rumors about the victim via internet (K).

A) Said nasty or insulting words using email or SMS; B) Said to others nasty words about the victim using internet or SMS; C) Threatened through messages via internet or SMS; D) Hacking of email account and extraction of personal information about the victim; E) Hacking of account and impersonating the victim (through instant messaging or social network accounts); F) Created a false account to impersonate the victim (Facebook or MSN); G) Posted personal information about the victim on the internet; H) Posted embarrassing videos or photos of the victim on the internet; I) Manipulated photos which the victim had posted on the internet; J) Excluded from or ignored by a social network or chat; K) Rumors spread about the victim via the internet.

Graph 2. Percentage of students, heterosexual (H) v. non-heterosexual (NH), who report having suffered each cybervictimization behavior.

As Graph 2 shows, in this case, sporadic threats are four times more common among non-heterosexual students; exclusion from social networks or chats is three times more common; and the spreading of rumors is six times more common. Furthermore, in this case, it is worth highlighting how different types of attacks on personal integrity, which in some cases do not even appear in heterosexual students, do appear in non-heterosexual students with percentages oscillating around 3%. This is the case of behaviors of posting or manipulating personal photos or videos on the internet; hacking personal accounts to obtain personal information, impersonating or creating false profiles on social networks; or the spreading of personal information about the victim on the internet.

Once again, these findings underline the specificity of this type of bullying because they demonstrate that, not only is there a greater prevalence of these types of aggressions in LGBT students, but that the type of aggression committed outlines a different profile to that of heterosexual students. Moreover, the results also lead to the conclusion that non-heterosexual orientation increases the probability of suffering bullying, thereby constituting a risk factor.

A study conducted in Spain in 2011 found that roughly 20% of young people manifested a clear rejection of sexual diversity, with 75% of young people aged between 15 and 29 having witnessed homophobic aggressions in their schools in the form of rumors, insults and slurs; 6.4% had seen beatings of lesbians, gays, bisexuals or transsexuals (INJUVE, 2011). This last point reinforces the idea of “stigma contagion” mentioned above. Likewise, these data help us understand the results of the GLSEN which show that 63.5% of non-heterosexual students state that they do not feel safe at school because of their sexual orientation (Kosciw, Greytak, Bartkiewicz, Boesen, & Palmer, 2012).

CONSEQUENCES

In terms of the consequences of this type of bullying we find, on the one hand, a certain similarity with “general” bullying, but we have also found, in line with what we have discussed in this chapter, a certain specificity probably associated with social homophobia and the previously mentioned lack of support.

The consequences of homophobic bullying share similarities with general bullying such as lack of sleep, loss of appetite, isolation, nervousness, anxiety, irascibility, anger, depression, low self-esteem, absenteeism, deceit and poor academic performance (Fineran, 2002; Marchueta, 2014; O’Shaughnessy, Russell, Heck, Calhoun, & Laub, 2004; Rivers & D’Augelli, 2001; Ryan & Rivers, 2003; Warwick Aggleton, & Oliver, 2000). Likewise, a clear relation has been found between this type of bullying and suicide attempts and self-harm (Dyson et al., 2003; Rivers, 2001). However, previous studies have found a greater prevalence of suicide attempts in LGBT youngsters in general, and in victims of homophobic bullying in particular. Rivers (1996) found that 20% of homosexuals and bisexuals interviewed in a social study had tried to commit suicide more than once during their adolescence. Besides, in a matched control study among a sample of same-sex and opposite-sex-attracted Secondary students, the former were more likely to report having symptoms of negative affects, after controlling for exposure to bullying behavior, than the latter (Rivers & Noret, 2008). In a representative study with 750 young Canadians, Bagley and Tremblay (1997) found that gays and bisexuals accounted for 62.5% of total suicide attempts and self-harm behaviors, meaning that they were 14 times more likely to commit suicide than their heterosexual peers.

In terms of bullying, Hershberger and D’Augelli (1995) found that 42% of young LGB Americans had tried to commit suicide on at least one occasion as a consequence of being victimized or isolated by peers, family or members of the community. More recently, the study by Generelo (2012) in Spain found that 43% of young LGBs between 12 and 25 who had been bullied because of their orientation had thought about committing suicide, with 17% having attempted it. In a study into the long-term consequences of bullying, 53% of lesbians and gays stated that they had thought about self-harming themselves as a consequence of being

victimized at school, and 40% indicated that they had tried to commit suicide on at least one occasion (Rivers, 2001).

Findings at a global level also show a greater risk of suicide among these adolescents (Russell, Ryan, Toomey, Diaz, & Sanchez, 2011; Saewyc, 2011; Toomey, Ryan, Diaz, Card, & Russell, 2010). In fact, the internalization of homophobia forms part of risk behaviors (Warwick & Douglas, 2001). As Gómez (2006) points out, the internalization of heterosexist messages and dealing with the prejudice which non-heterosexuality involves, produces emotional pain and wear and tear, leaving marks which are sometimes indelible. The results of research into self-harm behaviors amongst youngsters of sexual minorities suggest that both the personal and social negative assessments of homosexuality and bisexuality affect the mental health of people and their susceptibility to self-harm and suicidal behaviors (Rivers, 2011, p. 86). In turn, in the study mentioned earlier, Hershberger and D'Augelli (1995) found that the best predictor for mental health among young LGB people was self-acceptance. In the same vein, Birket, Espelage and Koenig (2009) showed how diverse negative results of LGBT students in terms of depression, suicide, drug abuse and school difficulties were related to contextual factors such as homophobic victimization and the climate at school, emphasizing school's capacity to eradicate these problems. Hence, it seems that the characteristics and response of the social setting are fundamental mediating elements in this type of violence.

CONCLUSION

Homophobic bullying is considered by UNESCO (2013) to be a universal phenomenon occurring in all countries, regardless of beliefs or cultures. The literature reviewed highlights how being part of a sexual minority currently constitutes a risk factor for being victimized. In turn, there are different reasons which suggest that homophobic bullying has characteristics which merit specific treatment. Specifically, social homophobia means that, in these cases, the silence of the victims intensifies because some students are reticent about explaining their situation to a teacher because they have previously observed examples of homophobia (or at least permissiveness towards it) in the school setting.

The fact that, as different studies have consistently shown, having a minority sexual orientation constitutes a risk factor for our youngsters is a basic violation of a person's right to full development. The invisibilization of minority sexual identities further isolates these young people. Some authors have related this to a range of negative consequences for mental health resulting from this type of bullying. The school, as a key socializing agent, should contribute to optimum personal development, avoiding the transmission of ideas which suggest the acceptance of certain forms of being against others and which reinforce discriminatory practices. This takes us to the need to visibilize diversity in schools in a way that respects the principle of the full development of personality which, as we have mentioned, represents a fundamental objective of education in a range of human rights declarations and legislation. As shown in some of the studies mentioned here, self-acceptance is a key element for mental health. It is therefore a duty for the school environment to foster the full development of the person, with this including gender identity and sexual orientation.

However, it is important to point out that this subject is undergoing a profound transformation owing to the change in how the subject of sexual diversity is considered in social

and legislative terms. Some recent studies have found more open attitudes towards sexual orientation, showing this as just one more aspect of the person and not the only or defining one (Taulke-Johnson, 2009 cit. en Rivers, 2011). Likewise, McCormak (2010) did not find any evidence of homophobia in two out of the three colleges studied. However, when this does happen most students do nothing to support the victim. Other studies have highlighted a change towards a more positive attitude regarding homosexuality amongst youngsters compared to older people (Anand, 2016).

Finally, it is important to reiterate that several studies have demonstrated school's capacity to eradicate these problems, showing how activities performed in the school context can help reduce both explicit and implicit prejudices, blurring the lines and promoting relations between groups (Birket et al., 2009). Similarly, several studies have shown the efficacy of programs aimed explicitly at reducing prejudices. Some have reflected the positive effects of programs in the school setting aimed at reducing prejudice towards transsexuality (Green, 2014; Steward, 2010). However, others aimed at reducing prejudice towards young LGBT students have not been effective (Mundy-Shephard, 2015). In the struggle against homophobic bullying, Cáceres and Salázar (2013) underlined the importance of the social context and the support given to this fight by educational and legal systems. They compared results from Chile, where its system is beginning to penalize discriminatory and homophobic attitudes, with Guatemala and Peru, countries where it is not penalized. They found that in Chile homophobic attitudes were becoming less frequent, at least at a public institutional level, while in Guatemala and Peru these attitudes were minimized, not rebuked or penalized as they were considered "annoying acts," but not bullying.

Thus, it is to be hoped that the legal and social changes which are occurring in different countries in terms of the equalizing of rights and the visibilization of sexual diversity will gradually translate into a progressive acceptance of LGBT students as a part of normality in the classroom. In fact, several meta-analyses have shown how contact with LGBT people reduces prejudice towards this group (Smith, Axelton, & Saucier, 2009; Pettigrew & Tropp, 2006). Hopefully, this greater visibilization and normality will be accompanied by a reduction in discrimination. However, the results reviewed highlight that there is still a long way to go before reaching that normalization. The actual characterization and understanding of homophobic bullying has not gone in parallel with the study of other related phenomena which have appeared relatively recently, such as cyberbullying. This reflects, on the one hand, the silence and prejudices that still surround the subject and, on the other, it highlights the need for further research to gain a deeper understanding of the phenomenon.

ACKNOWLEDGMENTS

This work has been developed within the framework of the Project "Sexting, cyberbullying y riesgos emergentes en la red: claves para su comprensión y respuesta educativa" [Sexting, cyberbullying and emerging risks on the internet: keys for their understanding and educational response] (EDU2013-44627-P) from National Research Plan (Government of Spain). The authors wish to express their gratitude for the support received.

Chapter 120

**THE ROLE OF ATTACHMENT STYLES
IN THE DEVELOPMENT OF AGGRESSIVE BEHAVIOR
AMONG PEERS: AN OVERVIEW ON HOMOPHOBIC
BULLYING WITH A VICTIM'S REPORT**

“Kore” University of Enna, Enna, Italy

ABSTRACT

Strong evidence suggests that attachment relationships developed during childhood can play a key role in the understanding of the process of affect regulation and interpersonal relationships in adolescence and adulthood (Bowlby, 1973, 1988; Pace, Zappulla, & Di Maggio, 2016). The human relationship, however, is not only the product of internal working models that the infant develops in childhood, but also, in a broader sense, a spin-off influence that derives from the social context (Bronfenbrenner, 1979; Bandura, 2001). Indeed, several authors point out how dysfunctional attachment predicts problematic relationships with others, including hostility and bullying among peers in adolescence (Ainsworth, 1979; Bowlby, 1978; Cassidy, 1994; Nickerson, Mele & Osborne-Oliver, 2009; Rispoli et al., 2013). This chapter will thus focus on the role of attachment in both the development of relationships during adolescence and the very genesis of bullying. The characteristics of homophobic bullying will be described together with the role of individual and social variables that can help to develop this phenomenon. A report on victims of homophobic bullying will then be presented in order to understand the nature of this phenomenon in greater depth.

ATTACHMENT AND AGGRESSIVE BEHAVIOR TOWARD PEERS

The affective relationship is at the heart of attachment theory as formulated by Bowlby who indicated how humans have an innate tendency to seek contact and proximity with others. Bowlby (1988), referring to the studies in ethology conducted by Harlow, deduced how a compartmental model exists to maintain proximity and nearness with others, particularly in times of distress. The attachment bond indicated a durable relationship that is characterized by affect and emotions with a significant other. To explain this, Bowlby (1979) used the term “working models” that describes how these models are used by a child to understand and predict his relationships with others in adolescent and adult life. In particular, the working models refer to how a child is acceptable or not for others, especially for parents. They are necessary to endow a child with trust and thus help him to “define” his world. “During adolescence and adult life, a measure of attachment behavior is commonly directed not only towards persons outside the family but also towards groups and institutions other than the family. A school or college, a work group, a religious group or a political group can come to constitute for many people a subordinate attachment-‘figure,’ and for some people a principal attachment-‘figure.’ In such cases, it is plausible to assume that the development of attachment to a group is mediated, at least initially, by attachment to a person holding a prominent position within that group [...]. That attachment behavior in adult life is a straightforward continuation of attachment behavior in childhood is shown by the circumstances that lead an adult’s attachment behavior to become more readily elicited. In sickness and calamity, adults often become demanding of others; in conditions of sudden danger or disaster a person will almost certainly seek proximity to another known and trusted person. In such circumstances an increase of attachment behavior is recognized by all as natural” (Bowlby, 1982, pp. 207-208). In others words, for Bowlby the attachment style influences future relationships. Mary Ainsworth (1979), also, through Strange Situations, identified the following styles of attachment: secure, insecure-avoidant and insecure-ambivalent. There is also another style identified by other Authors (Main & Salomon, 1985) that is the most problematic of all: disorganized attachment. Indeed, in the literature it is clear that if parents create a warm atmosphere and, at the same time, severely forbid behavior that is harming to others, they instil feelings of empathy in their children (Hoffman, 1984). Indeed, some studies underlined how children with secure attachment are more likely to develop internal representations of others as supportive and helpful, and to develop positive and satisfactory interpersonal relationships with others (Larose & Bernier, 2001; Meins, Bureau, & Fernyhough, 2017). However, the study conducted by Teti and Ablard (1989) has shown how secure attachment reduces aggressive behavior. In contrast, the study by Renken and colleagues (1989) has shown how insecure-avoidant attachment predicted aggression behavior in boys, whereas maternal hostility predicted aggression in both sexes. Other research showed how insecure attachment is connected with externalizing problems or behavioral problems, such as aggressiveness toward peers (Fagot & Kavanagh, 1990; Pace & Zappulla, 2010; Fearon et al., 2010, Pace & Zappulla, 2011). Nevertheless, some recent studies suggested how disorganized attachment is connected to aggressive behavior toward peers (Lyons-Ruth, Alpern, & Repacholi, 1993, Lyons-Ruth, 1996; Lecompte & Moss, 2014; Paetzold, Rholes, & Kohn, 2015). However, the attachment style is connected with bullying, which is considered to be a particular form of aggressiveness toward peers. Indeed, recent research underlines how secure attachment in children may be a protective factor against

involvement in bullying (e.g., Nickerson, Mele, & Princiotta, 2008; Murphy, Laible, & Augustine, 2017).

BULLYING IN ADOLESCENCE

During adolescence a manifestation of aggression among boys and girls is bullying. Adolescence is a critical and complex moment in which identity is forged and molded not only in relation to family models but also and especially as a function of the surrounding environment (e.g., the peer group) (Bandura, 2001). Bullying can be described as a phenomenon characterized by the implementation of aggressive behavior and repeated with a real power imbalance (Olweus, 1993). These aggressive and intentional behaviors are repeatedly manifested by one or more people, called bullies, toward a victim. Often the victim is unable to defend himself because sometimes he is smaller and/or weaker than his attacker(s). He does not receive adequate social support from his peer group and he is not willing or capable to meet the stereotypical roles of society. The bully's aim is to cause harm to another directly (through physical action such as kicking him, stealing or damaging personal property, etc.), or indirectly (via verbal and social exclusion, the spreading of gossip, etc.). In the literature, in addition to forms of direct and indirect bullying, there also exists cyber-bullying (where the behaviors between aggressors and victims are mediated through social media) and homophobic bullying.

CHARACTERISTICS OF THE BULLY AND HIS VICTIM

Bullying is a phenomenon which should be read especially in the ecological perspective (Bronfenbrenner, 1979), where individual and social variables are combined. Some studies have shown how anxious attachment is correlated with bullying attitudes. Respectively, anxious attachment was shown by girls to their mothers, by boys to their fathers (e.g., Williams & Kennedy, 2012). Moreover, it is quite clear how bullies show more positive attitudes towards the use of aggression compared to peers (Cole, Cornell, & Sheras, 2006). Therefore, anxious-ambivalent attachment has been seen in previous studies to be connected to interpersonal hostility (e.g., Lieberman, Doyle, & Markiewicz, 1999). Other studies have underlined how bullies, as well as being prone to aggression, have an impulsive temperament (e.g., Fite, Greening, & Stoppelbein, 2008; Passanisi & Pace, 2017). In addition, among the familiar features of the bully, the literature emphasizes that parental divorce (e.g., Malone et al., 2004), child maltreatment (e.g., Cullerton-Sen et al., 2008), an authoritarian parenting style (Lee & Song, 2012), inflexible and neglectful parents (Berger, 2007), encourage interpersonal aggression. However, social factors may also influence the acts of bullying. In homophobic bullying, forms of prejudices and stereotypes, such as social homophobia or sexism, may influence attitudes towards persons belonging to sexual minorities (e.g., Carrera-Fernández et al., 2014; Petrucci et al., 2015). In these cases a study has shown that secure attachment may be a protective factor for gay and lesbian people (Trub et al., 2016).

The victim of bullying can be passive or submissive or a bully-victim (who encourages the bully to act) (Olweus, 1996; Andreou, 2001). In most cases the victim remains passive and

weak. The research by Guarino, Lancellotti and Serantoni (2011) suggests how the victim is often devoid of high esteem and has little capacity to socialize with peers. The victims are chosen by the bully who knows that they will almost certainly not respond to acts of abuse. However, the study recently conducted by Sekol and Farrington (2016) has shown how male and female victims lacked self-esteem, presented neurotic personality traits and had a history of victimization. The victims have probably built an image of the self and others tainted with insecurity based, as they are, on ideas about themselves and their relationships dominated by mistrust and uncertainty. In a study by Mohr (2007), victims of bullying perceive their parents (especially fathers) as not being particularly affectionate.

In this phenomenon, another important figure is the helper of the victim. The literature has shown how the victim's helper is usually someone with secure attachment and high levels of empathy (e.g., Nickerson, Apples & Princiotta, 2008). Encouraging projects to promote empathic abilities is essential in promoting prosocial behavior among boys (e.g., Davis, 2015). Therefore, empathy is a *sine qua non* to tackle the phenomenon of the purely social nature of bullying such as homophobic bullying.

HOMOPHOBIC BULLYING: DEFINITIONS AND INFLUENTIAL FACTORS

In the literature, physical and verbal homophobic bullying is a popular form of aggression among school-age children (Poteat & Espelage, 2005). It is not only a form of aggression towards people belonging to sexual minorities but is also directed towards those who are perceived as such inasmuch as they do not adhere to the dominant models of masculinity and femininity (Kimmer & Mahler, 2003; Swearer et al., 2008). The victims of homophobic bullying, unlike other victims, have a more negative perception of school and higher levels of anxiety and depression than those who were targeted for other reasons (Swearer et al., 2008; Espelage et al., 2008). Unlike other forms of bullying, homophobic bullying is based on the socially-created climate of the classroom. The study conducted by Kosciw and colleagues (2012) has revealed how students in rural or / and small towns in Canada showed higher levels of victimization in schools based on sexual orientation. Indeed, the research conducted by Poteat (2008) has shown how homophobic and aggressive atmosphere of the group in turn encourages acts of a homophobic nature. It can be deduced that a purely homophobic climate is likely to reinforce prejudice according to which the only socially-accepted form of sexual orientation is heterosexual (heterosexist ideology) (e.g., Herek, 2004). Another study shows how non-adherence to gender roles is connected to acts of abuse of power (Friedman et al., 2006). Indeed, persons belonging to sexual minorities experience episodes of victimization, indulge in riskier behaviors (e.g., substance use), including sexual behaviour and suicidal ideation (e.g., Garofalo et al., 1998; Bontempo & D'Augelli, 2002; Friedman et al., 2006). A recent study showed that victimization is related to symptoms of anxiety and depressive nature and the use of alcohol (Tucker et al., 2016). Other research has identified victimization as often related to absenteeism in schools (Rivers, 2000; Fisher & Tanner-Smith, 2016) as well as suicidal ideation and acts of self-harm (Rivers, 2000). The fear of being victimized and losing friends because of sexual orientation can lead to social exclusion. Additionally, victims of homophobic bullying claim they have often suffered attacks in the presence of educators who did not intervene to defend them (e.g., Elze, 2003; Ryan & Rivers, 2003). Especially in adolescence, social support is a protective factor for gay boys and lesbian girls. Paying little or

no attention to these forms of abuse of power or aggressiveness toward peers leads to the normalization of acts of a homophobic nature. The victim, in this way, will remain trapped in the cycle of victimization, which may be a predisposing factor in the genesis of psychopathology. Moreover, in the literature, victimization is a homogeneous phenomenon. Indeed, there are many studies showing that incidents of victimization are not specific to particular periods of the life cycle, but can start at the primary school (e.g., Solomon, 2004), continue at high/middle school (e.g., Williams et al., 2005; Espelage et al., 2017) and carry on at university (e.g., Janoff, 2005; Okanlawon, 2017). Therefore, at school, thinking that homosexuality is only a transitional phase of development and that homophobic attacks are mere instances of bravado is a mistake because the problem is indirectly fueled (Dèttore, Antonelli, & Ristori, 2014). Certainly, secure attachment style in difficult and complex situations is a protective factor in adolescence because it helps to cope with moments of great emotional tension and to develop social competence (Zimmermann et al., 2001; Rispoli et al., 2013). However, investigating attachment in victims of homophobic bullying is not enough because, as we have seen, social-relational variables also impact on both the victim and the bully. Indeed, Allen and colleagues (2007) suggest the importance not only of secure attachment but also of the quality of relationships with peers. Adolescence is an important social-evolutionary stage in which individual factors are combined with those from the social context and relationships with peers. In this period the adolescent is engaged in both the construction of self and social group dynamics (e.g., family and peer group). Significant family ties represent a protective factor for gay and lesbian adolescents because they feel more secure (Herek, Gillis, & Cogan, 2009). In contrast, the study conducted by Poteat and colleagues (2011) points out how parental support does not moderate the effect on homophobic victimization. At the same time, during adolescence another important role is peer group attachment. The literature stresses how the homophobic culture of the peer group is able to foster homophobic attitudes and behavior in each member of the group in terms of social contagion (Poteat, 2007; Poteat, Espelage, & Green, 2007; Poteat, 2008). In other words, adolescents are afraid that if they help and / or side with the victim they may also be labeled as gay or lesbian. In addition, in order to be accepted by the group, adolescents may try to hide their homosexuality and hope not to be victimized. The study conducted by Costa and Davies (2012) conducted on a group of adolescents showed how high levels of homophobia and/or transphobia are connected with attachment to stereotypes and “traditional” gender representations (i.e., dominant culture), almost as if the study group had been forced into what Butler (2011) calls “compulsory heterosexuality”. Indeed, the victims of bullying are usually children who do not fall into the traditional definitions of masculinity. Conversely, in line with Allport’s contact theory (e.g., Petrucci et al., 2015), knowledge of or contact with the culture of sexual minorities can be associated with the reduction of prejudice towards gay and lesbian people.

HOMOPHOBIC BULLYING: A VICTIM’S REPORT

Luca¹ is a twenty-five-year-old boy from a small Sicilian town who suffered acts of homophobic bullying at school. He was administered an interview with open-ended questions

¹ Luca is a false name respecting the privacy of the person involved.

(Table 1 Interview schema) to help evoke the victimization suffered, and the Italian version of Ca-Mir (Molina, Critelli, & Pierrehumbert, 2007), to evaluate the attachment style.

L. says that he was victimized by all his peers, especially by males. Usually they called him by his name in the feminine version or with negative epithets. Furthermore, he was never chosen by peers for the various activities (whether in the classroom or outdoors). The more serious episodes happened during the third year of elementary school (approximately) and then continued through to middle school. In high school, however, L. was never invited by males for any activity. L. said that “maybe, they are ashamed of me.” These episodes began because he did not like football, and perhaps for the way he looked (thin and fragile). Once his peers teased him because he said he wanted to be a dancer. L. was often teased because he did not make any male chauvinist comments on females. He affirms that the bullying acts continued despite the fact that he had a girlfriend (he is not able to explain why). However, he often tried to conform to his peer group, pretending to be interested in football or things that his male companions typically did. L. wanted to be accepted. Especially, L. remembers that, during middle school, he was spared a few insults if he let his classmates copy his class work. The feelings that L. still feels today are anger and sadness. Specifically, L. remembers feeling almost invisible and often wrong.

Table 1. Interview schema

1. How and by whom have you been victimized?
2. How long did these episodes last and why do you think they happened?
3. How did you feel?
4. Have you ever tried to avoid these episodes in any way?
5. Have you ever thought of suicide?
6. Was there anyone who could help you?
7. Have you ever told anyone about these episodes?
8. How do you feel now (especially thinking back to these episodes)?

The feeling that he did not belong may be due to the fact that L. did not fit into male chauvinist stereotypes, present mainly in small towns. Fortunately, L. has never thought of suicide. The literature, indeed, underlines how these feelings are evident in bullied people. Notwithstanding this, his teachers did not usually perceive that these episodes were in fact occurring. He also remembers that it was almost taboo to talk about homosexuality in the classroom. Sometimes teachers do not perceive the significance of this phenomenon because of which the message that the male or female victim receives is: “you do not exist”/“the problem does not exist” (Dèttore, Antonelli, & Ristori, 2014). Furthermore, L. does not remember anyone ever taking his side. He says that sometimes if the offenses were too strong, someone would say to him “don’t think about it. Let it go!”. However, L. never talked about these episodes with anyone. He was afraid of feeling even “more wrong” for what he was and felt. In other words, L. felt the weight of a culturally stereotyped society (Butler, 2011). Despite the perceived lack of both social support and empathy, L. became resilient on his own, hoping that someone would help him. Today L. feels good and accomplished. He no longer thinks about the past acts of bullying and, if anyone does offend him now, he laughs about it. Recalling these episodes, he does not feel sad but he would like someone to understand him and his feelings.

From the administration of Ca-Mir, L. does not report problematic scores. The highest score, though one standard deviation below, concerns the scale “family distance” ($t = 59.8$). This finding may be related to the fact that L. has always managed his life on his own. He also suffered victimization without requesting the help of his parents and/or peers. Greater parental support would certainly have helped, even though he does not report problematic scores in the “parental support” scale ($t = 54.21$). The predominant attachment style, though one standard deviation below, is “detached attachment” ($t = 57.72$). Nevertheless, L. did want to manage his life on his own. Anyway, now L. has realized that the injury did not diminish his self-esteem. He may have set aside some dreams but he has surely developed an adequate resilience that can be used in critical situations.

This report helps us to understand not only that bullying is a far-reaching phenomenon, both emotionally and socially, but also that social and parenting support systems are crucial where the attachment style with internal working models focused on a secure base represents an important protective factor. Indeed, it would seem that parents often find it difficult to recognize and face their children’s problems, and may even use cognitive distortions to minimize or deny them. This occurs chiefly because parents fear they might otherwise invade their children’s “personal space” and therefore wait for them to ask for help, which of course may never happen. Greater awareness and training of teachers and parents on these important issues is thus called for. Surely, the individual characteristics of adolescence should not be overlooked because bullying, especially if homophobic, affects one’s emotional reactions. In conclusion, what seems to be lacking in the social groups of some cultures that are still rooted in prejudice is a “shared social grammar” (Caprara, 1992) that might otherwise implement social inclusion.

Chapter 121

**SUICIDAL BEHAVIOR IN ASSOCIATION
WITH IN-SCHOOL BULLYING IN
AFRICAN AMERICAN YOUTH**

ABSTRACT

Background: The purpose of this literature review was to examine the association of in-school bullying in connection to suicidal behavior in school aged youth, with a specific interest in African American adolescents. In addition, this article examined protective factors against suicidal behavior in adolescents. *Methods:* A thorough literature review was conducted using Academic Search Premier, Academic Search Complete, and Education Research Complete, Psychology and Behavioral Science Complete and various other educational research databases. The following search terms were used: bullying, bullying in adolescence, bullying in primary school aged students, bullying in school aged youth, African Americans and bullying, bullying and suicidal behavior, African Americans and suicide, suicidal risk factors and black adolescents. There were no restrictions on the year of publication, although preference was given to articles published within the last 15 years. A summary of each article was developed and analyzed for common themes. *Results:* Results indicated youth who experienced bullying behavior in conjunction with co-occurring risk factors, such as poor mental health and substance use were more likely to exhibit suicidal behavior in comparison to youth not experiencing co-occurring risk factors.

* Corresponding Author's Email: ashley.merianos@uc.edu.

Results also revealed parental connectedness, other adult connectedness, spirituality and school connectedness served as protective factors in school aged youth. *Discussion:* Going forward, anti-violence/in-school bullying prevention programs should incorporate self-esteem building curriculum in combination with activities that enhance parental involvement and school connectivity. In addition, research examining the relationship between in-school bullying and suicidal behavior in African American youth is scarce and warrants additional investigation. A more thorough examination of this population would allow for the development of more specialized programs better able to meet the needs of this populace.

Keywords: African Americans, bullying, suicidality

INTRODUCTION

According to the Centers for Disease Control and Prevention (CDC), suicide is defined as: “death caused by self-directed injurious behavior with any intent to die, whereas suicidal ideation is defined as the contemplation and or consideration of suicide (CDC, 2016a; CDC, 2014). A suicide attempt is defined as the direct result of a non-fatal attempt to take one’s own life; the attempt may or may not result in injury (CDC, 2016a; CDC, 2014). These various phases of suicidal behavior indicate suicide is rarely ever an isolated incident, but rather a culmination of thoughts, attitudes and behaviors potentially leading to suicide.

In 2015, firearms (49.8%), suffocation (26.8%), and poisoning (15.4%) were the top three methods used to commit suicide (American Foundation for Suicide Prevention, 2017; CDC, 2015). Research indicates females are more likely to attempt suicide in comparison to males; although many deaths related to suicide are attributed to male deaths (American Foundation for Suicide Prevention, 2017). Differences in suicidal behavior have also been observed on the basis of race/ethnicity, with Whites, Native Americans, Alaskan Natives, Asian and Pacific Islanders and African Americans having the highest rates of suicidal behavior, in this respective order (American Foundation for Suicide Prevention, 2017). Within the United States, suicide is the second leading cause of death in youth aged 10 to 24, with approximately 4,600 deaths resulting annually (National Vital Statistics System, National Center for Health Statistics, CDC, 2014; CDC, 2015).

According to the Youth Risk Behavior Survey (YRBS, 2016) females (23.4%) are more likely to seriously consider suicide in comparison to males (12.2%). With prevalence rates of having seriously contemplated suicide higher among Hispanic (18.9%) students in comparison to African American (14.5%) students (YRBS, 2016). Within the past year, 8.6% of high school students attempted suicide, with prevalence of attempted suicide higher in female students (11.6%) in comparison to male (5.5%) students (YRBS, 2016). Based on race, suicide attempts were higher in Hispanic (11.3%), African American (8.8%) and White (6.3%) students (YRBS, 2014).

Several risk factors have been associated with suicidal behavior in school aged youth, including: familial history, previous suicide attempts, history of mental illness, alcohol and/or drug abuse, and feelings of hopelessness (CDC, 2016b; Bazrafshan, Sharif, Molazem and Mani, 2016; Bhatta, Jefferis, Kavadas, Alemango and Shaffer-King, 2014; Wolfe, Foxwell and Kennard, 2014). Most strikingly, research also indicated youth involvement in bullying behavior was associated with increased suicidal behavior (Borowsky, Taliaferro and McMorris,

2013; CDC, 2014; Espelage and Holt, 2013; Kaminski and Fang, 2009; Klomek, Sourander, and Gould, 2010). Youth who reported involvement in bullying activity (bully, victim & bully-victim) displayed increased levels of suicidal behavior in comparison to youth who reported no involvement in bullying activity (Borowsky, Taliaferro and McMorris, 2013; CDC, 2014; Espelage and Holt, 2013; Kaminski and Fang, 2009). In addition, youth who indicated bully-victim behavior, showed higher rates of suicidal behavior in comparison to any other group of students indicating bullying behavior (Borowsky, Taliaferro and McMorris, 2013; CDC, 2014).

African American students were found to be an extremely vulnerable population, exhibiting a multiplicity of risk factors associated with bullying onset (Albdour & Krouse, 2014). Risk factors included low socioeconomic status, substance abuse, and exposure to high crime and violent environments (Albdour & Krouse, 2014; Bettencourt and Farrell, 2013; Demaray, Malecki, Davidson, Hodgson, and Rebus, 2005; Goldweber, Waasdorp and Bradshaw, 2013; Marsh and Cornell, 2001). Research has shown African American school-aged youth are more likely to be involved in bullying behavior in comparison to their Caucasian peers (Albdour & Krouse, 2014; Bettencourt and Farrell, 2013; Fitzpatrick, Dulin and Piko, 2010; Goldweber, Waasdorp and Bradshaw, 2013; Low and Espelage, 2013; McDade, King, Vidourek, 2017; Wang, Iannotti, and Nansel, 2009).

Currently, research has been able to link bullying activity to suicidal behavior (CDC, 2014). However, researchers are unable to delineate a clear causal pathway by which bullying involvement influences suicidality (CDC, 2014). The purpose of this literature review was to examine the causal pathway between in-school bullying and suicidal behavior in African American Adolescents.

METHODS

A thorough literature review was conducted using Academic Search Premier, Academic Search Complete, and Education Research Complete, Psychology and Behavioral Science Complete and various other educational research databases. The following search terms were used: bullying and suicidal behavior, bullying in adolescence, African Americans and bullying, black adolescents and suicidal risk factors. There were no restrictions on the year of publications, although preference was given to articles published within the last fifteen years.

RESULTS

The present literature review indicated a significant link between bullying behavior and suicidality. Bullying behavior in association with substance abuse and/or poor mental health have both been shown to increase risks for suicidal behavior and provide a mediation pathway for suicidality. Examination of the following articles provided further insight into the causal relationship between in-school bullying behavior and suicidality.

Klomek et al., (2011) were one of the first to examine the longitudinal effects of bullying in relation to mental illness and suicidality. Participants included 9th through 12th grade high school students from the state of New York, USA; baseline data were observed, followed by a four-year follow-up. Three distinct groups were identified at baseline: Bully Only, At Risk

Only, and At Risk Bully (Klomek et al., 2011). The “Bully Only” group was asymptomatic of depression, suicidal behavior, and substance use. The “At Risk Only” group presented with depressive symptoms and suicidal behavior and substance use in the absence of bullying. The “At Risk Bully” group presented with depressive symptoms, suicidal behavior and involvement in bullying activities (Klomek et al., 2011). At follow up, the “Bully Only” group was significantly less likely to report depression, suicidal behavior, and substance use problems in comparison to the other “At Risk” groups (Klomek et al., 2011). Youth in the “At-Risk Bully” group were also more likely to report poor mental health, increased substance use and suicidal behavior in comparison to the “At-Risk Only” group.

In a previous study conducted by Mitchell, Ybarra, and Finkelhor (2007), investigators examined the relationship between victimization (online/internet and offline/in person) and depressive symptomology, high delinquency, and substance use. Sample size consisted of 1,501 youth, ages 10-17; a phone survey methodology was utilized. Results showed youth experiencing multiple types of offline-victimization (physical assault, theft, sexual assault, etc.) were significantly more likely to report depressive symptomology, high delinquency (stealing, damage to property, physical assault, and being picked up by police) and substance use in comparison to youth not experiencing these various forms of offline bullying. In a similar study conducted by Litweller and Braush (2007), authors examined two models: 1) The relationship between online (cyber) victimization and suicidal behavior and 2) The relationship between offline (physical) victimization and suicidal behavior. Violent behavior, substance use and sexual behavior were tested as mediators between the two forms of bullying and suicidal behavior. Results indicated both physical bullying and cyber bullying had a significant direct effect on all three-mediating variables. Substance use and violent behavior were shown to have a significant direct effect on suicidal behavior for both models; effect of sexual behavior on suicidal behavior was not significant. Also, the overall effect for both physical and cyberbullying on suicidal behavior was significant.

Lardier, Barrios, Garcia-Reid and Reid (2016) examined the relationship between in-school bullying and suicidal ideation via mediative factors including: family conflict, depressive symptoms and substance use. The sample size consisted of 488 adolescents 10-18 years of age, from a northern New Jersey suburban community. Study findings indicated when mediators were added, the relationship between bullying and suicidal ideation was no longer significant. Two significant pathways emerged: 1) school bullying in the presence of family conflict mediated suicidal ideation and 2) school bullying in the presense of family conflict and depression mediated suicidal ideation. Both pathways were significant for both men and women. In addition, two other significant pathways for females only emerged: 3) school bullying in the presense of depression mediated suicidal ideation and 4) school bullying in the presense of depression and substance use mediated suicidal ideation.

In a study conducted by Stewart, Valeri, Esposito, and Auerbach (2017) researchers examined non-suicidal self-injury behaviors and risky behavior engagement as potential mediators between peer victimization (overt and indirect {reputational e.g., another teen gossiped about me and relational e.g., a teen left me out of what they were doing}) and suicidal thoughts and behaviors (suicidal plan and suicidal attempt). The sample population consisted of 349 depressed adolescents ages 13-19 within 48 hours of admission for acute psychiatric treatment. Path analysis indicated both the direct effects of overt victimization on suicide attempts and indirect effects through risky behavior engagement were significant. Concerning indirect victimization, path analysis indicated a significant direct effect of reputational

victimization on suicide attempts and a mediating effect via risky behavior engagement. There were no significant direct effect or indirect effects of relational victimization on suicide plans; Path analysis was not reported for relational victimization on suicide attempts.

Mitchell et al., (2016) examined depression, perceived burdensomeness (perceived ideology that one's death is worth more to others than one's life) and thwarted belongingness (extreme isolation and disconnection from others and lack of reciprocal caring relationships) as potential mediators between cyberbullying and suicidal ideation. Mediation analysis indicated that cyberbullying, perceived burdensomeness and depression had significant direct effects on suicidal ideation. Path analysis also showed perceived burdensomeness has a significant effect on thwarted belongingness; however, thwarted belongingness does not have a direct effect on suicidal ideation.

A predominant amount of literature has explored risk factors associated with in-school bullying and suicidality. Less research has explored protective factors against suicidality in relation to in-school bullying. We now shift gears to further explore protective factors associated with this public health disparity.

Fitzpatrick, Piko, and Miller (2008) examined protective factors in association with suicidal ideation and suicide attempts in African American adolescents in grades 5-12 in southeastern United States. Regression analysis indicated students who reported higher levels of self-esteem were less likely to engage in suicidal behavior (ideation and/or attempt). Analyses also indicated students were significantly less like to engage in suicidal ideation when a part of a spiritual community. In a study conducted by Borowsky, Taliaferro and McMorris (2013) researchers examined protective factors against suicidal behavior in association with verbal/social bullying among junior high and high school students in Minnesota. Students were categorized into three groups: perpetrator only (perpetrated once a week or more, and victimized less than once a week), victim only (victimized once a week or more, and perpetrated less than once a week), and perpetrator and victim (victimized and perpetrated once a week or more). Results indicated parent connectedness and friends caring were significant protector factors against thinking about or attempting suicide across all three groups; other adults caring was a significant protective factor for the perpetrator and the victim only group. In a similar study, Taliaferro and Muehlenkamp (2014) examined protective factors against against suicidality in 9th and 12th high school students in Minnesota. Three research questions emerged: 1) protective factors differentiating adolescents who engage in suicidal ideation versus adolescents who do not engage in suicidal ideation; 2) protective factors differentiating adolescents who engage in suicide attempts versus adolescents who do not engage in suicide attempts; and 3) protective factors differentiating adolescents who engage in suicide attempts versus adolescents who engage in suicidal ideation only. For both males and females, parent connectedness was a significant protective factor across all three groups. Concerning suicidal ideation versus suicidal attempt, students were significantly less likely to engage in suicidal attempt in the presence of academic achievement and perceived neighborhood safety. Additional significant protective factors that emerged included sports participation, friends caring and school safety; protective factors were not significant across all groups. Stone, Luo, Lippy and McIntosh (2015) examined protective factors associated with minority sexual youth (students identifying as homosexual or bisexual) in connection to suicidality in high school students. Regression analysis indicated minority sexual youth who reported higher rates of parent connectedness, other adult connectedness, and school connectedness were significantly

less likely to engage in suicidal ideation. Concerning suicidal attempt, only parent connectedness and other adult connectedness proved to be statistically significant.

DISCUSSION

Upon completion of a thorough literature review, it is most evident bullying in and of itself is not always a direct causal factor for suicidal behavior. More often than not, results indicate involvement in bullying activities, in association with poor mental health (e.g., depression, low self-esteem, and perceived burdensomeness) and/or substance use precipitate suicidal behavior in youth. Poor mental health has been consistently identified as a precursor to involvement in risky behavior (Dual Diagnosis, 2017). Research also indicated involvement in risky behavior is often utilized as a coping mechanism to lessen the effects of physical and emotional trauma (Lardier, Barrios, Garcia-Reid and Reid, 2016; Jackson, Seth, DiClemente and Lin, 2015). As a result, inhibitions may decrease therefore allowing youth to more easily engage in suicidal behaviors (Sinyor and Cheung, 2014; Mitchell, Ybarra and Finkelhor 2007). This pathway seems to be represented within the Litweller and Braush (2007) article, in which substance use and violent behavior were shown to have direct impacts on suicidal behavior.

Both Taliaferro and Muehlenkamp (2014) and Stewart et al., (2017) showed youth were more likely to attempt suicide in the presence of mental/emotional health problems and self-injurious behavior. This aligns with the Interpersonal Psychological Theory of Suicidal Behavior (Joiner, 2017), which posits both the desire to die and the capability to do so, must both be present before suicide can take place. A person must hold two overarching states of mind, a sense of perceived burdensomeness and a sense of low belongingness (emotional/mental health problems). In addition, a person will no longer fear death, and will have developed a fearlessness of pain and injury via repetitive exposure to harmful stimuli, such as self-injury (Joiner, 2017).

Concerning protective factors, the presence of parent connectedness and friends caring were the most consistent shielding influences against suicidal behavior in adolescents across multiple studies (Borowsky, Taliaferro and McMorris, 2013; Taliaferro and Muehlenkamp, 2014; Stone, Luo, Lippy and McIntosh, 2011). Parent connectedness and friends caring allows youth to have a strong support system within their immediate circle, which provides adolescents with the emotional and physical supports needed to withstand stressful stimuli (Taliaferro and Muehlenkamp, 2014). Other adults caring was also a significant protective factor; additional support may provide youth with a more robust social backing that enhances school connectivity and thwarts bullying onset (Whitlock, Wyman, and Moore, 2014). Specifically in African Americans, self-esteem was shown to be a significant protective factor against suicidal ideation and suicide attempt, whereas being apart of a spiritual community was a significant protective factor against suicidal ideation, but not suicide attempt (Fitzpatrick, Piko, Miller, 2008). Within the African American community, “the church” has typically been the nucleus or apex within this population (Austin and Harris, 2011; Hays, 2015). Close ties to a spiritual community allow for the development of a cultural stigma towards taking one’s own life (Marion and Range, 2003; Walker, 2007). This overarching norm may prevent youth from engaging in such behavior because of the shame and disgrace associated with suicidality. The presence of hope, family connectedness and effective coping strategies were also seen to buffer against suicidal behavior

in African American college students. (Davidson, Wingate, Sligh, & Rasmussen, 2010; Wang et al., 2013). Within the African American community, suicide is regarded as a “White Persons” issue in addition to being deemed immoral (Davidson et al., 2010; Walker, 2007). These ideologies provide a cornerstone on which individuals base their decisions, thus protecting this population against engaging in suicidal behavior. Although this data was not specific to African American adolescents, it still provides insight into protective factors specifically associated with African Americans.

LIMITATIONS

Articles utilized in this literature review were restricted to papers written in English. Preference was also given to articles written in the past 15 years. In addition, articles examining the relationship between in-school bullying and suicidality were not specific to African American adolescent populations, as literature was not in extreme abundance for this populace.

RECOMMENDATIONS

Future research should focus on the examination of in-school bullying and suicidality specifically within African American youth. African American youth are drastically under-researched in this topic area, which is especially apparent for studies utilizing mediative analysis to determine suicide causality. Most studies have examined this health disparity across groups (e.g., race, age and sexual orientation) versus within one group (e.g., African Americans). Further examination would allow investigators to determine risks and protective factors unique to this population. Moving forward, anti-violence/in-school bullying prevention programs should incorporate self-esteem building curriculum in combination with activities that promote parental involvement and school connectedness.

Chapter 122

BIOPSYCHOSOCIAL DIFFERENTIAL PREDICTORS OF SUICIDE AND BULLYING

***Andrea D. Mata, PhD, Lacey E. Grogan
and Caitlin Shellenbarger, MA***
University of Findlay, OH, US

ABSTRACT

Suicide, the second leading cause of death for 15-29 year olds globally (WHO, 2017), is undoubtedly connected to another ubiquitous problem during adolescence, bullying. However, the connection between suicide and bullying is misunderstood at times, because some believe that bullying causes suicide. Psychological research conveys a different picture in that it shows that suicidal ideation and suicidal behavior represent possible risks for adolescents who experience bullying. Being bullied, however, does not cause suicidal ideation or suicidal behavior because not everyone who is bullied engages in suicidality. The limitation of previous research is that most previous research focuses on the individuals who experience suicidal thoughts and behaviors after they have been bullied. Far fewer research investigates factors that differentiate those who were bullied and experienced suicidal thoughts and behaviors compared to those who did not. This study used data from 2,386 7th through 12th graders who completed Wave I of Add Health. Results revealed that sex, grade point average, self-esteem, depression, optimism, sense of school belongingness, and closeness to both mothers and fathers differentiated youth who were bullied and experienced suicidality compared to youth who were bullied and did not experience suicidality. Implications of these findings for intervention programming are discussed.

Adolescence consists of a time when there are numerous ubiquitous problems, some of the most notable being suicidality and bullying. Suicidality includes both suicidal ideation and suicidal behavior. More specifically, suicidal ideation is when an individual thinks about or wishes to end their life, while suicidal behavior consists of nonfatal events (van Geel, Vedder, & Tanilon, 2014). Suicidality has become a public health concern, given that suicide is the second leading cause of death for individuals between the ages of 15 through 29 years (WHO, 2017). This declaration is understandable given that suicide is perceived to be largely

preventable, and it seems non-sensible that 5,491 adolescents took their own lives in 2015 (American Association of Suicidology, 2017). When looking at suicidality longitudinally, utilizing the Youth Risk Behavior Surveillance Survey (Kann et al., 2016), suicidal ideation and making a suicide plan has increased since 2009. However, suicidal behavior has shown an overall decreasing trend since 1991. In 2015, 17.7%, 14.6%, and 8.6% of youth reported they “seriously considered attempting suicide”, “made a suicide plan”, and attempted suicide, respectively (Kann et al., 2016).

A second ubiquitous issue during adolescence—bullying—includes the following aspects: repeated harassment, a power differential between bully and victim, and the bully possessing an intent to harm the victim (Smith & Brain, 2000). Bullying includes different modes such as in person or electronic (Smith & Slonge, 2010) and includes different types such as physical, verbal, or relational abuse (Hoover, Oliver, & Hazler, 1992; van Geel et al., 2014). For ease of understanding this chapter, we use bullying and peer victimization interchangeably. When examining peer victimization prevalence rates roughly over the last decade, the rates have been relatively stable since 2009 (Kann et al., 2016). The 2015 Youth Risk Behavior Surveillance Survey found that 20.2% and 15.5% of high schoolers reported peer victimization at school and stated that they experienced electronic peer victimization in the past 12 months, respectively (Kann et al., 2016).

Given the ubiquitous nature of these two aforementioned problems during adolescence, it is logical that people began pairing them. Simply based on the information in the previous two paragraphs, it appears that there is something about 2009 that changed in both suicidality and bullying. Wayne (2013) argued that this change may be at least partially explained by how the U.S. news media has covered stories that involved both suicide and bullying. She posited that prior to 2008, when a story involved a youth suicide, the article did not mention bullying. However, after 2008, bullying became a standard explanation for any youth who committed suicide (Wayne, 2013). Now it appears common place for youth who commit suicide after being victims of peer victimization to receive an abundance of publicity (Marr & Field, 2001; Wayne, 2013). As much as media would like us to believe, and as hard as they push this agenda, empirical evidence alludes to a positive correlation between suicidality and bullying, not a causal relationship.

SUICIDALITY AND BULLYING

The body of research over the past two decades has established an association between suicidality and peer victimization (Barzilay et al., 2017). More specifically, peer victimization increased the risk of suicidal ideation by 2.23 times for every one unit increase of peer victimization, whereas peer victimization increased the risk of suicidal behavior by 2.55 times for every one unit increase of peer victimization (van Geel et al., 2014). These results are demonstrated for both children and adolescents, and for a variety of modes of peer victimization—bullying in school or via electronic methods. Now with that said, the type of peer victimization—physical compared to relational victimization—demonstrated differences with suicidality (Barzilay et al., 2017). Physical peer victimization increased the likelihood of suicidal ideation by 39%, whereas relational peer victimization increased suicidal behavior by 28% (Barzilay et al., 2017).

The pattern of these results suggests that the association between suicidality and peer victimization is significant and moderate in strength (Holt et al., 2015). However, it is not a one to one correlation. This means that it is not a causal relationship, as US media would like us to believe. The association appears to be best described as multifinality (Cicchetti & Toth, 1998)—in other words, not all those who experience peer victimization react with suicidality (Bonanno & Hymel, 2010).

BIOPSYCHOSOCIAL MODEL

One major limitation of the previous research on the association between suicidality and peer victimization consists of focusing on the basic association, and not investigating the fact that a greater percentage of youth do not react with suicidality as a way to cope with being victimized by their peers (Bonanno & Hymel, 2010). More specifically, Bonanno & Hymel (2010) found that suicidal ideation and peer victimization had a zero order correlation of .24. This focus on the basic association prevents a comprehensive view of what factors serve as risk and protective factors. Therefore, we may need a different way to understand the association between suicidality and bullying.

Considering the body of literature on the association between suicidality and peer victimization, we have opted to apply a biopsychosocial approach (Engel, 1977) to the fact that a substantial percentage of youth who experience peer victimization do not become suicidal. The biopsychosocial approach posits that to better understand human behaviors, we need to adopt a systemic view (Engel 1980)—one that incorporates biological, psychological and social factors of the behavior of interest. Biological factors include the biological vulnerability each of us of have for a certain behavior or mental illness, mostly due to our genetics or our biochemical make-up (Engel, 1977). Whereas psychological factors incorporate aspects of the person such as mood, personality, and behavior (Engel, 1977). Lastly, social factors include how an individual is impacted by cultural or familial aspects of their lives (Engel, 1977). By adopting a biopsychosocial approach, we can investigate how a variety of factors differentially predict those who are bullied and react with suicidality compared to those who do not in one sample.

Biological Factors

Sex

One of the most significant factors to consider when attempting to better understand suicide, is the individual's sex. It is well documented that females report more suicidal ideation and are more likely to attempt suicide, whereas males are more likely to successfully complete suicide (Kirkcaldy, Eysenck, & Siefen, 2004; Lewinsohn, Rohde, Seeley, & Baldwin, 2001).

When considering sex differences on prevalence rates of the broad conceptualization of peer victimization, the results are equivocal (Carlyle & Steinman, 2007). However, when the different types of peer victimization were considered, the results became more consistent—males were more likely to report physical and verbal peer victimization, whereas females reported higher levels of relational victimization (Barzilay et al., 2017).

When sex is investigated as a moderator for the association between suicide and bullying, again, the results are inconsistent—some previous studies have found that the risk of suicide to be higher for males who have been bullied (Laukkanen, Hintikka, Hintikka, & Lehtonen, 2005), whereas other studies demonstrate the risk of suicidality to be higher for females who have been bullied (Klomek, Sourander, & Gould., 2010). Finally, in an attempt to shed more light on these inconsistencies, Holt and colleagues (2015) investigated sex as a moderator in their meta-analysis and found that overall, sex did not moderate the association between suicidality and bullying. This pattern of results across multiple empirical articles may be inconsistent, but it appears that sex still needs to be included whenever the association between suicidality and peer victimization is investigated.

Cognitive Faculties

The next factor that may shed some light on differentiating the groups, deals with individuals' cognitive faculties—whether those are conceptualized as intelligence, cognitive deficits, or grade point average. For example, adolescents with lower grade point averages reported higher levels of suicidal ideation (Field, Miguel, & Sanders, 2001). Additionally, individuals with increased cognitive deficits were more likely to attempt suicide compared to individuals with fewer cognitive deficits (Huntington & Bender, 1993).

When investigating the impact of intelligence on peer victimization, Bowes and colleagues (2010) found that youth with lower intelligence possessed a lower likelihood of being both emotionally and behaviorally resilient to the effects of peer victimization. Additionally, youth who were bullied demonstrated lower grades and lower scores on standardized assessments of achievement (Nakamoto & Schwartz, 2009). Given these findings, we wanted to discover if cognitive faculties would act as differential predictor of those who are bullied and experience suicidality from those who are bullied and do not experience suicidality.

Psychological Factors

Self-Esteem

Self-esteem has a profound effect on a person's thoughts, feelings, and actions (Kernis, 1993; Trzesniewski, et al., 2006). The associations between both suicidality and peer victimization with self-esteem consistently shows the same direction—a negative one. In other words, those who experienced peer victimization reported lower self-esteem (O'Moore & Kirkham, 2001), and those who reported lower levels of self-esteem were more likely to report suicidal ideation (Wilburn & Smith, 2005). Wrapping our heads around the complete picture of these associations would suggest that self-esteem may mediate the association between suicidality and peer victimization. Therefore, this study will investigate the differential predictive ability of self-esteem between those who experience peer victimization and report suicidality compared to youth who experience peer victimization and do not report suicidality.

Depression

Depression is typically included in studies that explore suicidality (Field et al., 2001) because it is commonly believed that depression is a good warning sign of suicidality (Borowsky, Taliaferro, & McMorris, 2013). However, the association between suicidality and depression shows to be much more complex. Research typically shows that mild to moderate

levels of depression predict suicidal ideation, however, extreme levels of depression do not predict suicidal ideation (Field et al., 2001). This finding supports previous research and clinical intuition that individuals who are severely depressed are not at great risk for suicide. This is because they most likely lack the energy and motivation to engage in most everyday behaviors, let alone behaviors that entail taking their life (Auerbach, Millner, Stewart, & Esposito, 2015; Mittal, Brown, & Shorter, 2009).

When investigating the association between peer victimization and depression, the research supports a positive association for both immediate and delayed elevation (Stapinski, Araya, Heron, Montgomery, & Stallard, 2015). In other words, youth who experienced victimization reported higher levels of depression both immediately and later on.

Optimism

Optimism can be defined as a belief that the good will prevail in future outcomes (Scheier & Carver, 1985). Not a lot of research has been conducted on the relationship between optimism with neither suicide or bullying. Therefore, we have decided to include empirical support on a construct that is the opposite of optimism—hopelessness. The relationship between hopelessness and suicidality is so strong that hopelessness is typically viewed as a warning sign for suicide (Lester, McSwain, & Gunn, 2011). Empirical studies have demonstrated that individuals who attempted suicide reported higher levels of hopelessness compared to non-attempters (Morano, Cisler, & Lemerond, 1993). Somewhat surprisingly, research does not support a relationship between peer victimization and hopelessness (Siyahhan, Aricak, Cayirdag-Acar, 2012).

Social

In Joiner's Interpersonal Psychological Model of Suicide (Joiner, 2005), he posits that individuals become more suicidal when they lack interpersonal connections—a construct he coined as thwarted belongingness. This model was created with adults in mind, however, in recent years, researchers have tested whether this model also applies to adolescents (Jones, Schinka, van Dulmen, Bossarte, & Swahn, 2011).

Sense of School Belongingness

In Mata et al. (2012), the connection was made between suicidality and bullying, stating that bullying during adolescence characterizes thwarted belongingness. In that paper, they investigated the role of school belongingness on the relationship between participation in extracurricular activities and suicidality. They found that, generally, youth who participated in extracurricular activities demonstrated lower levels of suicidality through their increased connection to school (Mata, et al., 2012). Therefore, a sense of connection to the school was important for suicidality. However, we want to investigate what other social relationships during adolescence are important in reducing the connection between suicidality and bullying.

Closeness to Parents

Building off of this previous work, adolescents who reported better relationships and closeness with their parents also reported lower levels of suicidality (Field et al., 2001; Kandel, Raveis, & Davies, 1991). Similarly, adolescents who reported that their parents were not readily

involved in their lives were also more likely to be bullied compared to adolescents with parents who were more involved in their lives (Flouri & Buchanan, 2003).

Closeness to Friends

Parents continue to play a role in their adolescents' lives. However, we would be remised to solely focus on parents instead of friends. We know that throughout adolescence, adolescents become more influenced by their friends compared to their parents (Brown, Lohr, & McClenahan, 1986). Participants who were classified into a suicidal ideation group reported significantly fewer friends, worse peer relations, and were less popular compared to adolescent participants who were not classified in the suicidal ideation group (Field et al., 2001). Throughout adolescence, Borowsky et al. (2013) reported that perceived caring by friends was a protective factor across those who were victims of bullying. Additionally, victims of peer victimization typically showed lower peer acceptance compared to their peers who had not experienced peer victimization (Borowsky et al., 2013).

CURRENT STUDY

The goal of this study is to better understand what factors differentiate youth who are bullied and experience suicidality from those who are bullied and do not experience suicidality. Utilizing a biopsychosocial model, we plan to investigate if sex, cognitive faculties, self-esteem, depression, optimism, sense of school belongingness, and closeness to mother, father and friends differentiate these two groups of youth. It is our hope that the findings from this study will inform intervention programming to address the association between suicidality and peer victimization.

METHODS

Participants

This study used data from Wave I of the National Longitudinal Study of Adolescent to Adult Health (Add Health; Bearman, Jones, & Udry, 1997). An in-school questionnaire was distributed to more than 20,000 students from 132 schools during the 1994-1995 school year. We limited the sample to include only those participants who reported experiencing some form of physical peer victimization in the past 12 months and those who had data on all of the study variables. Through a screening of suicidality and victimization, the sample size of 2,386 students from grades 7 through 12 was created. The sample consisted of more males (73%) than females (27%). The average age of the participants in the current sample was 16.29. The distribution of ethnicity in our sample was 46.8% White, 17.8% Black, 10.2% Hispanic, 6.9% Asian, and 17.7% Other.

Measures

Suicidality. We operationalized suicidality as suicidal ideation and suicidal behavior. Suicidal ideation was measured with one dichotomous item, inquiring whether the participant had seriously thought about committing suicide during the past 12 months. Suicidal behavior was measured using a five-point scale (0 times, 1 time, 2 or 3 times, 4 or 5 times, 6 or more times), but we dichotomized it (no reported suicidal behavior = 0, 1 time = 1) for the present study due to the low frequency of the higher responses (Kaminski & Fang, 2009). In our sample, 20% of the adolescents experienced suicidal ideation and 7.1% reported at least one incident of suicidal behavior in the past 12 months.

Peer Victimization. The peer victimization variable was constructed using four items: the participant had experienced a knife or a gun being pulled on him/her, someone shooting him/her, someone cutting or stabbing him/her, or being jumped (Kaminski & Fang, 2009). For these four items, the participants identified from a range of never (0) to more than once (2) that each of these events occurred in the past 12 months. The vast majority of our sample (63.2%) solely experienced one of these items, followed by 25.8%, 9.4%, and 1.6% of our sample reporting that they experienced two, three, or four of these physical peer victimization items in the past 12 months, respectively. Similar to the suicidal behavior items, we dichotomized the participants' responses to distinguish if the participant had reported being physically victimized by their peers or not.

Based on participants responses from the two suicidalities and the peer victimization items, we created four groups: those who were bullied and did not experience suicidal ideation ($N = 1908$; 80%), those who were bullied and experienced suicidal ideation ($N = 478$; 20%), those who were bullied and did not attempt suicide ($N = 2216$; 93%), and those who were bullied and attempted suicide ($N = 170$; 7%).

Biological Factors

Grade Point Average

For this study, grade point average (GPA) serves as an assessment/ proxy for the participants' cognitive faculties. The participants reported during their last school year, whether they earned an A, B, C, or a D or lower in the following subjects: English/Language Arts, Mathematics, History/Social Science, and Science. We recoded the four items so that higher scores on these four items were indicative of earning the more desirable grades (e.g., A's). The four items were averaged ($\alpha = .69$) and the mean GPA score for our sample was 2.51 ($SD = .76$).

Psychological Factors

Self-Esteem

Self-esteem was measured using five items: one believing he/she had a lot of good qualities, he/she had a lot to be proud of, he/she liked himself/herself just the way he/she was, he/she felt he/she was doing everything just about right, and he/she felt socially accepted. Participants reported on a five-point Likert scale whether or not they strongly agreed (1) or

strongly disagreed (5) with these five items. We opted to recode these five items so that higher scores on these five items represented more positive views of oneself. These five items were averaged ($\alpha = .80$) and the mean self-esteem score for our sample was 4.02 (SD = .62).

Depression

Depression was measured with 15 items: he/she had been bothered by things, had poor appetite, had the blues, felt he/she was just as good as other people, had trouble focusing, felt depressed, felt too tired, hopeful about the future, felt that life was a failure, felt fearful, felt happy, talked less, felt lonely, sensed people were unfriendly, and enjoy life. Participants reported on a four-point Likert scale whether or not they never/rarely (0) or most/all of the time (3) experienced these 15 items. We opted to recode four items (felt he/she was not as good as other people, hopeful about the future, felt happy, enjoy life) due to them being reversed coded in the original data collection. For these the 11 normally coded and four recoded items, higher scores suggest higher levels of depression. The 11 normally coded and four recoded items were averaged ($\alpha = .82$) and the mean depression score for our sample was .73 (SD = .42).

Optimism

Optimism was measured by four items: likelihood of whether he/she would live to age 35, if they would be married by age 25, if they would be killed by age 21, and if he/she will get HIV/AIDS. Participants chose using a five-point Likert scale the likelihood that these events would occur from almost no chance (1) to almost certain (5). We recoded two items (chances killed by age 21, chances get HIV/AIDS) so that higher scores on the items indicated a more positive outlook on their life. The two originally coded and two recoded items were averaged ($\alpha = .44$) and the mean optimism score for the sample was 3.99 (SD = .58).

Social Factors

Sense of School Belongingness

Closeness to school was measured utilizing three items: whether one felt close to people at his/her school, felt like he/she were a part of his/her school, and he/she was happy to be at school. These three items were measured on a five-point Likert scale in which the adolescent could indicate the degree to which they agreed (1 = strongly agree) or disagreed (5 strongly disagreed) with each of the statements. We recoded these three items so that higher scores on them indicated higher levels of closeness to school and then averaged the three recoded items ($\alpha = .76$). The mean score of closeness to school was 3.55 (SD = .92).

Closeness to Mother and Father

Closeness to mother and father was measured using the same five questions but separate items for mother and father: mother/father was warm and loving, if he/she was satisfied with how they communicate, and if he/she was satisfied overall with the relationship to the mother/father, how close he/she felt to your mother/father, how much did he/she think the mother/father cared about him/her. For the first three listed questions, participants reported on a five-point Likert scale whether they strongly agreed (1) or strongly disagreed (5). We recoded these three items (mother/father was warm and loving, if he/she was satisfied with how they communicate, and if he/she was satisfied overall with the relationship to the mother/father) so

that higher scores reflected higher levels of closeness with the respective parent. For the latter two questions, participants were asked on a five-point Likert scale (1 = not at all, 5 = very much) whether they were close to their respective parent and whether they believed the respective parent cared about them. We averaged the three recoded questions and the two originally coded items for mothers ($\alpha = .83$) and fathers ($\alpha = .88$) separately. The mean score of closeness to mother was 4.33 (SD = .66) whereas the mean score of closeness to father was 4.09 (SD = .82).

Closeness to Friends

Closeness to friends was measured with one item: how much one felt his/her friends cared about him/her. The participants used a five-point Likert scale (1 = not at all, 5 = very much) for this item, where higher scores indicated higher levels of closeness to friends. The mean score of closeness to friends was 4.14 (SD = .82).

RESULTS

Biological Factors

Sex

Chi-square analyses indicated a statistically significant association between biological sex and both suicide ideation ($X^2(1) = 64.588, p < .001$) and suicide attempt ($X^2(1) = 62.29, p < .001$). Of those who were bullied and engaged in suicidal ideation, 30.9% were females while 16.0% were females. Of those who were bullied and attempted suicide, 14.0% were females while 4.6% were males. In other words, these results suggest that females are 2.33 and 3.38 times more likely to engage in suicidal ideation and attempt suicide as a result of being bullied compared to males, respectively.

Grade Point Average

A statistically significant difference on GPA was revealed between individuals who attempted suicide and those who did not ($t_{2384} = 2.26, p < .05$). Those who attempted suicide earned a lower GPA ($M = 2.38, SD = .81$) compared to those who did not attempt suicide ($M = 2.52, SD = .77$).

Psychological Factors

Self-Esteem

An independent samples t-test found a statistically significant difference in self-esteem scores between participants who engaged in suicidal ideation and those who did not ($t_{660.48} = 11.55, p < .001$). Those who did not engage in suicidal ideation ($M = 4.1, SD = .58$) reported higher self-esteem compared to those who did ($M = 3.7, SD = .68$). A statistically significant difference in self-esteem scores was also shown between those who attempted suicide and those who did not ($t_{183.98} = 7.67, p < .001$). Those who did not attempt suicide demonstrated higher self-esteem ($M = 4.06, SD = .59$) compared to those who did ($M = 3.58, SD = .79$).

Depression

Depression scores were statistically significantly different between those who engaged in suicidal ideation and those who did not ($t_{624.67} = -15.87, p < .001$). Those who engaged in suicidal ideation reported higher depression scores ($M = 1.03, SD = .48$) compared to those who did not ($M = .65, SD = .37$). Similarly, there was a statistically significant difference in depression scores between those who attempted suicide and those who did not ($t_{185.33} = -11.76, p < .001$). Individuals who attempted suicide reported higher depression scores ($M = 1.16, SD = .51$) compared to those who did not attempt suicide ($M = .69, SD = .38$).

Optimism

Those who engaged in suicidal ideation had statistically significantly different optimism scores compared to those who did not ($t_{690.33} = 5.84, p < .001$). Participants who engaged in suicidal ideation exhibited less optimism ($M = 3.85, SD = .62$) compared to those who did not ($M = 4.03, SD = .57$). Similarly, there was a statistically significant difference in optimism between those who attempted suicide and those who did not ($t_{190.71} = 4.80, p < .001$). Those who attempted suicide also showed less optimism ($M = 3.77, SD = .64$) compared to those who did not ($M = 4.01, SD = .58$).

Social Factors***Sense of School Belongingness***

There was a statistically significant difference in school belongingness between those who engaged in suicidal ideation and those who did not ($t_{666.28} = 5.43, p < .001$). Those who engaged in suicidal ideation reported less feelings of school belongingness ($M = 3.33, SD = 1.02$) compared to those who did not ($M = 3.60, SD = .88$). Additionally, there was also a statistically significant difference in school belongingness scores between those who attempted suicide and those who did not ($t_{186.93} = 4.44, p < .001$). Those who attempted suicide reported less school belongingness ($M = 3.19, SD = 1.09$) compared to those who did not attempt suicide ($M = 3.58, SD = .90$).

Closeness to Mother

There was a statistically significant difference between those who engaged in suicidal ideation and those who did not regarding closeness to their mother ($t_{641.60} = 8.70, p < .001$). Those who engaged in suicidal ideation reported lower scores ($M = 4.07, SD = .76$) compared to those who did not engage in suicidal ideation ($M = 4.40, SD = .62$). There was also a statistically significant difference regarding closeness to their mother between those who attempted suicide and those who did not ($t_{187.53} = 5.86, p < .001$). Those who attempted suicide demonstrated lower scores ($M = 4.00, SD = .77$) than those who did not attempt suicide ($M = 4.36, SD = .65$).

Closeness to Father

Levels of closeness to one's father were statistically significantly different between those who engaged in suicidal ideation and those who did not ($t_{641.58} = 9.01, p < .001$). Those who

engaged in suicidal ideation reported lower scores ($M = 3.76$, $SD = .94$) compared to those who did not ($M = 4.18$, $SD = .76$). Similarly, there was a significant difference regarding closeness to their father between those who attempted suicide and those who did not ($t_{187.52} = 4.63$, $p < .001$). Those who attempted suicide showed lower scores ($M = 3.77$, $SD = .95$) compared to those who did not ($M = 4.12$, $SD = .80$).

Closeness to Friends

Regarding closeness to friends, there were no statistically significant differences between those who engaged in suicidal ideation compared to those who did not ($t_{697.25} = -.42$, $p = .691$), or between those who attempted suicide compared to those who did not ($t_{187.57} = -.75$, $p = .45$).

DISCUSSION

This was the first investigation, at least to our knowledge, that applied the biopsychosocial model to investigate the differential predictors of youth who are victimized by their peers and react with suicidality compared to youth who are victimized by their peers and do not respond with suicidality. The pattern of our results suggests that biological, psychological, and social factors differentiate these two groups.

In regards to sex, the results show the direction we expected for suicidality, given the previous research demonstrating that females are more likely to think about killing themselves and attempt suicide, whereas males are more likely to complete suicide (Kirkcaldy et al., 2004; Lewinsohn et al., 2001). The pattern of findings from the current study support findings from Klomek and colleagues (2010), in that females appear to be more impacted by bullying compared to males. Females were found to be 2.33 and 3.38 times more likely to react to bullying with a form of suicidality, compared to males. This suggestion makes inherent sense, given that bullying is very much a behavior that falls in the realm of relatedness—and we know that females are socialized to be more interpersonal (Sanathara, Gardner, Prescott, & Kendler, 2003). Therefore, if females are victimized by their peers they may take it harder compared to their male counterparts, and react with suicidality. McBride and Bagby (2006) made a similar argument to help explain why females are more prone to depression—they argued that because females are more interpersonal, they are more vulnerable to depression. In this current study, sex differentially predicted which adolescents exhibited suicidality due to experiencing peer victimization—females. In other words, being female statistically significantly increased the likelihood that a youth would experience suicidality as a result of being victimized by their peers.

The second biological factor that differentiated the two groups—cognitive faculties—demonstrated an interesting pattern. Grade point average differentially predicted when suicidal behavior was the outcome variable, but not when suicidal ideation was the outcome variable. Therefore, this finding suggests that cognitive faculties may mean more for suicidal behavior compared to suicidal ideation. People with higher cognitive faculties may experience suicidal ideation at the same rate as youth with lower cognitive faculties, however, youth with higher cognitive faculties may not leap to the level of suicidal behavior because they may be able to contemplate alternative options. This finding may be explained in that youth who have the ability to consider other options do not experience the high levels of hopelessness as a reaction

to being victimized by their peers. They may have the ability to engage in a cognitive coping skill such as reattribution—in that they consider that maybe their peer is victimizing them because of something external to themselves and internal to the bully.

All three psychological factors differentially predicted the two groups of youth who experienced suicidality as a result of being victimized by their peers. In other words, those who function better psychologically—have higher levels of self-esteem, lower levels of depression, and higher levels of optimism—are less likely to engage in suicidality in reaction to being victimized by their peers. These three psychological factors may serve as proxies for coping skills that the individual youth possess. It very well may be that the youth who function better psychologically may have more coping skills, and it is these coping skills that allow the majority of youth not to react with suicidality as a result of peer victimization.

Considering the social factors in our model, the pattern of results with the exception of the statistically non-significant results for closeness to friends, provides further support for Joiner's Interpersonal Psychological Model of Suicide (Joiner, 2005) and, more specifically, the construct of thwarted belongingness. A sense of being close to their mother and/or father and a belonging at their high school seems to be a strong protective factor against suicidality for youth who have been bullied. These three constructs further support previous findings that feeling like belonging (Mata et al., 2012) and having attachments (Borowsky et al., 2013; Fields et al., 2001) makes youth less likely to respond with suicidality when bullied.

The one interesting non-statistically significant finding in the realm of social factors was that closeness to friends did not differentially predict the different groups. One explanation for this null finding is how we measured closeness to friends—solely with one item. However, Borowsky and colleagues (2013) found that closeness to friends, using the exact item that we used, was statistically significantly associated with a reduction in suicidality for youth who have been bullied. The major difference between this study and Borowsky and colleagues' (2013) study was not only the sample, but the way they conceptualized suicidality—they combined suicidal ideation and suicidal behavior into one outcome variable. However, separating suicidality into suicidal ideation and suicidal behavior remains important in research, given that the majority of research demonstrates that different results occur when using these two as the main outcomes (van Geel et al., 2014).

Our findings further provide evidence that US news media has exaggerated the association between suicidality and peer victimization. In our sample, which was made up solely of individuals who had been victimized by their peers, a mere 7% reacted to this victimization with suicidal behavior. Even when considering the more prevalent suicidality outcome variable, suicidal ideation, only 20% of our sample reported suicidal ideation in response to being victimized by their peers. Putting these numbers into practical use, simply means that based off of statistics, only 1 in 5 children who are bullied will report experiencing suicidal ideation, and the odds are even smaller for youth who experience suicidal behavior in response to being victimized by peers.

Based on this pattern of results, it appears that experiencing peer victimization is a stressful life event—and those who have more developed coping skills and are socially connected are less likely to react with suicidality. Therefore, it appears that if society would like to further reduce the number of youth who react with suicidality after being victimized by their peers from 20% for suicidal ideation and 7% for suicidal behavior, then we need to adopt and implement intervention programs that would provide our youth with more coping skills. This suggestion corresponds nicely with recent empirical findings demonstrating that the generation

that is currently enrolled in college possess significantly fewer coping skills compared to previous generations (Chew & Thompson, 2014; Wilson, 2015).

The future directions of this study include searching for or developing a program that focuses on aiding youth in the development of coping skills, in an attempt to reduce suicidality in response to bullying. We argue that society should take a more individual route when it comes to intervention, in addition to or in replacement of anti-bullying programming. We take this stance for multiple reasons. First, a meta-analysis reviewed high quality anti-bullying programming that was based on empirical evidence, and found that these types of programs reduced bullying by 20 to 23% (Ttofi & Farrington, 2009). We acknowledge that this is a wonderful reduction. However, we are cognizant of the fact that the meta-analysis solely included programs that were high quality and empirically based (Ttofi & Farrington, 2009). Therefore, not all, and probably not the majority, of anti-bullying programming that is implemented across the nation in high schools consists of one of these high quality and empirical supported programs.

The second reason we are taking this stance of focusing more on helping youth develop coping skills to address the issue of bullying placing some of our youth at risk for suicidality, is that as previously mentioned, youth desperately need more coping skills (Chew & Thompson, 2014; Wilson, 2015). Implementing a program that focused on all youth developing coping skills would not only address the association between suicidality and bullying, but it could also significantly reduce the sheer number of youth being diagnosed with psychological disorders. Comparatively, anti-bullying programs are much more specific in the behaviors they are targeting and hence, students may not generalize the gained knowledge and skills from these programs to their everyday lives.

Given that it appears that bullying is considered a stressful life event, developers of this program would be well-advised to dive into the Clinical Health Psychology literature on how to develop coping skills to address stressful life events. Based on our findings, we believe that a program that would help increase reattribution skills, self-esteem, optimism and social bonds, and decrease depression would be a good start.

Like all other studies, this study is not without limitations. The primary limitation of this study is that we used secondary data analysis and therefore, we were restricted by the questions that were asked. This might have most notably been an issue with how we constructed the closeness to friends construct—solely with one item. Had we collected our own data, we would have measured closeness to friends with multiple items, possibly including a measure on friendship quality.

Additionally, we did not utilize the longitudinal nature of Add Health. We simply looked at how these variables were associated with each other when investigating the different constructs over the past 12 months. Therefore, we do not know whether suicidality is driving these associations, or whether the biopsychosocial factors or bullying is driving the associations. This will need to be teased apart in future studies.

The third limitation of the current study consists of when the Add Health data was collected, considering the importance of 2008 and 2009 for the suicide and bullying association. The Add Health team collected the utilized data in 1994 and 1995—this is a full decade prior to when the connection between suicidality and bullying was first introduced. The findings may not be replicated if a study utilized data from a more recent time period. However, this study can serve as a jumping-off point for use to collect more recent data.

Chapter 123

MODELING BULLYING PROPAGATION IN GREECE

Universitat Politècnica de València, Valencia, Spain

ABSTRACT

Bullying can be defined as an unwanted, aggressive behavior among school aged children that involves a real or perceived power imbalance. The behavior is repeated, or has the potential to be repeated, over time. Both kids who is bullied and who bullies others may have serious, lasting problems. The aim of this chapter is to forecast and quantify the propagation of bullying in the Greek school population aged [12, 18] during the period July 2015- January 2020. Finally, the results obtained are compared with the situation in Spain.

Keywords: bullying, Greece, propagation, forecast, victim, aggressor, outsider, defender

INTRODUCTION

Bullying is a social phenomenon in a universal range. A large number of studies conducted in different countries indicate that bullying at school occurs all over the world and is not confined to any geographical region, socioeconomic or cultural group. The involvement in bullying and victimization can affect on children concerning their psychology, behavior, emotions, academic career, and social consequences, as well as their mental and physical health, [1].

Literature shows scarce researchers trying to analyze this phenomenon in Greece. According to a recent research about bullying behavior in Greek schools [2], approximately one in five students is involved in incidents related to bullying at least once a month. The

* Corresponding Author's Email: elpopla@esp.upv.es.

percentage decreases to four students in one hundred, referring to a weekly basis of involvement.

Moreover, it has been observed a strong cross-sectional association between frequent victimization and suicidal ideation in late adolescence [3]. Victims of bullying behavior, especially those who were bullied on a weekly basis, were apt to express suicidal ideation. On the other hand, the perpetrators were not as much sensitive to express similar behavior as the aforementioned team.

A recent research in 2016 [4] provides a quantitative and qualitative aspect on bullying propagation in Greek schools, taking into consideration the family's socioeconomic situation, the reason of the victimization, the gender of the participants, and their feelings and reactions on these occasions. Also, the reaction of the teachers is necessary because the students come to them for mentioning bullying behaviors and policies to deal with this phenomenon. According to the results obtained, approximately one in three students has become a victim and, likewise, a perpetrator during the years of education. As far as the gender, males participate more often in bullying in comparison with females. Moreover, only two in ten students choose to express their feelings and mention possible events to their teachers. On the contrary, they prefer to talk to their parents, friends or not at all. Finally, but importantly, the results show that the main reason for victimization is the ancestry of the victim. This fact is highly important if someone considers the present situation of the country (financial-economic crisis; immigration from Middle East countries; Greek emigration; etc.).

This chapter focuses on applying a population dynamics model [5] to forecast the propagation of bullying in a Greek school population aged (12, 18) over the period from July 2015 to January 2020, by taking into account qualitative and quantitative factors. Additionally, one of the main aims of this chapter is to provide a comparison between the number of victims in Greek schools and the number of victims in Spanish schools over the same period of study following [5]. Following [5], we replicate the same model for the particular case of Greece. Thus, we present the study population; then, the transition coefficients are modelled and the mathematical model applied is shown. Afterwards, results are presented and a sensitivity analysis is performed. To conclude the study, the bullying propagation in Greece is compared with the situation in Spain and conclusions are detailed.

STUDY POPULATION

The target study (S) population embraces all Greek schoolchildren whose ages fall within the interval (12, 18) during the study period, which went from July 2015 to January 2020.

The first hypothesis of the model construction consists in splitting the population into five categories, as in [5-7], and by paying attention to the active, passive or neutral role adopted by students in the event of bullying:

- Victims (V)
- Defenders (D)
- Outsiders (O)
- Cooperators (C)
- Aggressors (A)

The study period from July 2015 to July 2020 was split into semesters, where $n = 0$ is the initial study time and corresponds to July 2015.

The vector of subpopulations (1) represents the amounts of subpopulations after n semesters.

$$X(n) = [V(n), D(n), O(n), C(n), A(n)]^T \quad (1)$$

Then the study population (S) quantifies the total of subpopulations at the beginning of our study period (July 2015).

Thus $S(0) = 723,404$ is the population aged (12,18) in July 2015 in Greece, [8]. Next, we obtained the initial subpopulations in July 2015 by collecting and managing data from [4]. Below we provide the numbers of scholars and the percentage that each subpopulation represents:

- $V(0) = 261,149$, victims represent 36.1% of $S(0)$
- $D(0) = 44,489$, defenders represent 6.15% of $S(0)$
- $O(0) = 116,034$, outsiders represent 16.04% of $S(0)$
- $C(0) = 67,494$, cooperators represent 9.33% of $S(0)$
- $A(0) = 234,238$, aggressors represent 32.38% of $S(0)$

Following [5] both $V(n)$ and $A(n)$ are cumulative categories that grow continuously during the study period because the condition of being a victim or aggressor remained with time. This implies that those who became victims in the first semester (July 2015) would still be considered victims in July 2020, $V(10)$.

MODELING TRANSITION COEFFICIENTS

In this section we explain very briefly the transit coefficients. Since this study is an application of the model proposed by [5].

Thus, we assumed that the net balance of the demographic change was equally distributed according to the initial proportions of each subpopulation at the initial time, $n = 0$, which corresponded to July 2015. We denote the demographic net balance by the notation*. This coefficient was assumed constant for the study period.

We denoted the vector of the net demographic balance by:

$$P^* = [V^*, D^*, O^*, C^*, A^*]^T \quad (2)$$

The net demographic balance provides an amount of incomers, expressed as follows following [5]:

$$P^* = \begin{bmatrix} V^* \\ D^* \\ O^* \\ C^* \\ A^* \end{bmatrix} = \frac{(Z-H)}{2} \cdot r = \frac{(Z-H)}{2} \cdot \begin{bmatrix} 0.361 \\ 0.0615 \\ 0.1604 \\ 0.0933 \\ 0.3238 \end{bmatrix} \quad (3)$$

where $Z=107,661$ represents the new incomers into the system; $H=115,074$ is the sum of those who left the system as they had reached the age of 19, along with the annual rate of mortality and the net migration amount, [8].

Then r is the vector that contains the original proportion of each subpopulation.

Following [5], the coefficients $\beta(DV)$, $\beta(OV)$, $\beta(OD)$, $\beta(CO)$, $\alpha(DO)$ were assumed constant for the study period. (see Table 2).

On the contrary, the coefficients $\alpha_n(OC)$ and $\alpha_n(CA)$ are depending on the rate of unemployment in Greece, so they were computed as follows:

$$\begin{aligned}\alpha_n(OC) &= 0.06 - \frac{1}{2} \cdot 0.01 \cdot dn \\ \alpha_n(CA) &= 0.05 - \frac{1}{2} \cdot 0.01 \cdot dn\end{aligned}\quad (4)$$

where dn is the employ recovery rate per semester.

Table 1. The Greek unemployment rates for the period 2016-2020

Year	Unemployment rate (%)
01/2016	24.3
07/2016	23.3
01/2017	23.2
07/2017	22.2
01/2018	21.7
07/2018	21.3
01/2019	20.9
07/2019	20.5
01/2020	20.1
07/2020	19.8

Source: OECD, Hellenic Statistical Authority and tradingeconomics.com.

Mathematical Model and Simulations

The mathematical formulation of the model is as expressed as follows according to [5]:

$$\begin{aligned}V(n+1) &= V(n) + \beta(DV) \cdot D(n) + \beta(OV) \cdot O(n) + V^* \\ D(n+1) &= \beta(OD) \cdot O(n) + (1 - \beta(DV) - \alpha(DO)) \cdot D(n) + D^* \\ O(n+1) &= \alpha(DO) \cdot D(n) + \beta(CO) \cdot C(n) + (1 - \beta(OV) - \beta(OD) - \alpha_n(OC)) \cdot O(n) + O^* \\ C(n+1) &= \alpha_n(OC) \cdot O(n) + (1 - \beta(CO) - \alpha_n(CA)) \cdot C(n) + C^* \\ A(n+1) &= A(n) + \alpha_n(CA) \cdot C(n) + A^*\end{aligned}\quad (5)$$

Then by computing the difference system of model equations and subpopulations $V(n)$, $D(n)$, $O(n)$, $C(n)$ and $A(n)$ for each semester, we forecasted the subpopulations expected at the end of semester n and, in particular, at the end of the study period (July 2020).

RESULTS

In this section we firstly show each subpopulation size according to the assumed hypotheses (see Table 4), along with the relative proportion of each subpopulation at the initial time, $n = 0$ and $n = 10$ (see Table 3).

As the category of victims and aggressors was cumulative, we considered interesting to estimate the semester variation of both categories (see Table 5). The increase in victims was higher than 1% per semester. This observation indicated that measures should be implemented to break this pattern.

Sensitivity Analysis

The transit coefficient $\beta(DV)$ was built based on the hypotheses of the random meetings occurring between defenders and victims according to [5]. Then, it was assumed a probability about 0.1 due to the approximate amount of victims (36.1%) obtained from the data at the beginning of the study (July 2015). However due to the uncertainty about the value adopted by the parameter, a sensitivity analysis was performed by changing this probability.

Table 5. Forecast growth of victims and aggressors per semester for the period 2016-2020

	$V(n + 1) - V(n)$	$A(n + 1) - A(n)$
n = 1 (January 2016)	3,652	1,938
n = 2 (July 2016)	3,473	1,596
n = 3 (January 2017)	3,310	1,389
n = 4 (July 2017)	3,146	1,222
n = 5 (January 2018)	2,995	1,191
n = 6 (July 2018)	2,842	1,075
n = 7 (January 2019)	2,691	950
n = 8 (July 2019)	2,541	836
n = 9 (Janurary 2020)	2,394	731
n = 10 (July 2020)	2,250	654

Figure 2. Sensitivity analysis of the victim subpopulations to the $\beta(DV)$ values at $n = 10$ ($\times 1000$).

Comparison between Greece and Spain

Following, we compared the subpopulations of victims and aggressors of Greek and Spanish [3] populations (table 7 and 8). As we can observe, at the beginning of the research ($n = 0$) (see Table 7), there was a great difference between the two countries according to the number of victims and aggressors. More extensively, the difference of number of the victims is 26.8% and of the number of the aggressors is 22.48% .

As time goes by, the amount of the populations of each country are getting closer. Specifically, at the end of the research ($n = 10$) (see Table 8), the difference of number of the victims is 17.74% and of the number of the aggressors is 14.54% Figure 3 and 4 draw both populations in Spain and Greece during the study period.

Table 7. Populations of victims and aggressors share, expressed as a percentage at the beginning of the research ($n = 0$)

	Victims	Aggressors
Spain	9.30%	9.90%
Greece	36.1%	32.38%

CONCLUSION

In this chapter, we applied a dynamic population model developed by [5] that reckons with sociological factors, such as demography, economy, culture, consumption of drugs, alcohol and social contagion. The proposed model quantifies the amount of victims and aggressors of school bullying in Greece by assuming that the policy does not change over a short study period.

During this research, we follow two assumptions: at first, the victims and aggressors categories are cumulative. Furthermore, there is no recovery about the category of aggressors. They can potentially express themselves in other violent ways, for example, against their partners or the members of their families.

We quantified the measure of this phenomenon in Greece and according to the results, the trend of the victims, as much the aggressors, are quite high. That means that the victimization of a child in the school area is much more common than we may think. Society as a whole needs to pay attention to this phenomenon. Initially, the government must apply the appropriate measurements in schools. Moreover, the teachers should remain watchful for possible cases and, finally, the family members have to listen to and take care of their children.

Chapter 124

ADDRESSING THE PROBLEMS OF BULLYING IN SCHOOLS IN THE UNITED ARAB EMIRATES

Ken Rigby (PhD), Dalia Haroun* (PhD) and Essam Ali

COUNTRY CONTEXT

The United Arab Emirates (UAE) is a federated high income country, covering approximately 83,000 square kilometres with just over 9.1 million people.¹ The UAE became a Federal State in 1971, and it comprises 7 Emirates: Abu Dhabi, Dubai, Ajman, Al-Fujairah, Sharjah, Umm Al-Quwain, and Ras Al-Khaimah. The three largest Emirates *Abu Dhabi, Dubai, and Sharjah* - are home to nearly 85% of the population. All seven Emirates have a large degree of independence and substantial spending on health, education, and social protection programmes.² For 2015, the UAE has a human development index (HDI) value of 0.840, placing it in the very high human development category with a rank of 42 out of 188 countries and territories.³ Basic provisions for the rights of children in the areas of health, education, and child protection are provided under Federal Law No. 3 of 2016 on Child Rights (*‘Wadeema’s Law’*).⁴ While the majority religion is Islam, the UAE has a legal framework and customs of tolerance for other cultures and beliefs.

UAE Vision 2021 aspires for all Emiratis to have equal opportunity to a first-rate education and to achieve their full potential. Schools are expected to nurture well-rounded citizens, confident and ready to play an active and positive role in society. Key elements are⁵:

⁴ Federal Law No. 3 of 2016, Issued on 08/03/2016, corresponding to 28 Jumada Al-Awwal 1437 H.

⁵ UAE, Vision 2021, Ibid. 10.

- A progressive national curriculum that encompasses critical thinking and practical abilities,
- Achieving ambitious educational targets, including high scores on standard international examinations,
- Reducing school drop-outs, enhancing vocational education, and increasing university and post-graduate enrolments
- Integrating special needs students within the education system, along with support programmes and infrastructure that guarantee fair access.

Recent policies and strategies that continue to promote and protect the rights of children include the Ministry of Education Strategy 2010-2020, which aims to improve the performance of Emirati children in science, math, and English, and reduce drop-out, especially at the upper-secondary level (cycle 3).

Education is compulsory for all Emirati children aged five and above, including expatriate residents. The public schools are government-funded and the curriculum is created to match the UAE development's goals and values. The medium of instruction in the public school is Arabic, and English as a Second Language is emphasized. There are also many private schools which are internationally accredited. Public schools in the country are free for all UAE Nationals up to university level, while the fees for private schools vary. Non-UAE nationals may attend public schools as fee-paying students. The public education system in the UAE is comprised of different cycles: cycle 1 includes grades 1-5 (6-11 years); cycle 2 grades 6-9 (12-15 years) and cycle 3 grades 10-12 (16-18 years). All government/public schools are gender segregated.

INTRODUCTION

Over the last twenty five years or so bullying in schools has increasingly been the subject of research in many countries. Bullying has been defined in general terms as the systematic abuse of power and takes various forms, both physical and non-physical (Smith and Sharp, 1994). The negative effects of school bullying on the health and wellbeing of children, both short term and long term, has been widely documented (Rigby, 1998, 2003). More recently studies have confirmed that bullying can lead to clinical depression (Ford et al., 2017) and to suicidal ideation (Lardier et al., 2016). Such findings have raised widespread interest among educators in how bullying in schools could be reduced and the negative effects of bullying on the health and well-being of school children thereby prevented.

For the most part the relevant research has been conducted in western countries, more especially in Europe and North America. Only recently has such research been undertaken in Arab countries. Based upon a literature search of research publications on bullying in the Arab world, Kazarian and Ammar (2013) identified only one empirical study providing data on bullying prevalence in Arab schools. Conducted in 2004/2005 that study reported by Fleming and Jacobsen (2010) included estimates of bullying prevalence among students aged 13-16 years attending schools in Jordan, Lebanon, Oman and the United Arab Emirates. Based upon the proportion of students in a survey reporting that they had been bullied at least once during

the previous month, figures ranged from 20.9% (UAE) to 44.2% (Jordan). Results for the UAE indicated that boys were being bullied more frequently than girls and that the level of bullying reduced as students got older. No distinction was made in the reports between the different forms of bullying experienced by students, such as verbal, physical and through cyber technology. The prevalence of cyber bullying worldwide has, however, been estimated in a survey reported in 2012 by Cross-Tab Marketing Services and Telecommunications Research Group for Microsoft Corporation [internet]. In the UAE it was estimated 7% had been targeted in this way.

In the 2005 UAE Global School Health Survey (GSHS), an overall 20.8% of 13-15 years old students were bullied on one or more days during the past 30 days (Ministry of Health, 2005). Male students (24.5%) are significantly more likely than female students (17.2%) to be bullied on one or more days. Among students who were bullied during the past 30 days, 15% were bullied most often by being hit, kicked, pushed, shoved around, or locked indoors. Victims of bullying had increased stress and a reduced ability to concentrate and are at increased risk for substance abuse, aggressive behavior and suicide attempts. The 2010 GSHS survey showed an increase in prevalence of bullying in the UAE, with the percentage of students who were bullied on one or more days during the past 30 days increased to 22.8%, with male students (25.8%) significantly more likely than female students (20.7%) to be bullied (Ministry of Health, 2010). A more recent international report on bullying across 47 countries has estimated that on average 29% of students report being bullied on a monthly basis (Mullis et al., 2016). The figure for the UAE of 31% was slightly higher than the international average.

UAE PROGRAM

In 2014, UNICEF Gulf Area Office (GAO) in cooperation with UAE Supreme Council for Motherhood and Childhood (SCMC) carried out a preliminary situation analysis of the school environment in the UAE to develop a framework for the protection and safety in the school and learning environment. UNICEF GAO's experts visited a total of 11 schools (primary and middle schools) across different Emirates to assess the school environment through conducting focus group discussions with the students, school staff, parents and school management, in addition to individual interviews and observations. Results from the preliminary school assessment indicated an increase in bullying behaviour in schools especially among cycle II students (aged 11-15 years).

Some of the key findings of the preliminary assessment include:

- Students were subjected to bullying amongst each other;
- Students were subjected to bullying by their teachers;
- Younger students (11-12 years) were more frank about the problems they experienced;
- Verbal bullying was the most common form of bullying;
- Students were under constant surveillance by the school staff;
- School staff and parents did not acknowledge the negative impact of bullying on children;
- Parents were not actively involved in their children's school.

In 2014, due to the unavailability of an anti-bullying and anti-violence program in schools in the Gulf and the needs for such a program, a seminar was organized by UNICEF GAO and SCMC to present successful models of anti-bullying programs in schools in their respective countries (Olweus program in the United States, and KIVA programs in Finland), in the presence of all relevant authorities mainly from the health and education authorities. The main aim of the seminar was to highlight the prevalence of bullying worldwide and the negative impact this has on students; hence initiating the process of developing a bullying prevention model suitable for implementation in schools in the UAE. The seminar resulted in forming a national committee to oversee the implementation of the program.

In 2015, UNICEF GAO with SCMC and Education Authorities in the UAE developed a school-based anti-bullying program. The program was under the patronage of Her Highness Sheikha Fatima bint Mubarak, Supreme Chairwoman of the Family Development Foundation, Chairwoman of General Women's Union, Chairwoman of the Supreme Council for Motherhood and Childhood. A total of 44 international school anti-bullying programs were extensively reviewed. The intervention adopted was in some respects similar to ones employed in some other countries, for example, the program designed to improve social and emotional learning (see Brown et al., 2011) delivered in classrooms and for which claims have been made regarding its effectiveness in reducing bullying. But in addition, the intervention utilised in this study provided classroom instructions directly concerned with improving knowledge of bullying and ways of addressing the problem. To deliver this program, teachers made use of manuals developed for the project, one focussing on the development of appropriate social skills, the other on addressing bullying directly. Teachers were instructed that they could choose from the lessons described in the manuals. Figure 1 provides a summary with examples of the themes and content of the lessons that were provided.

Bullying	Social Skills
1. Recognizing bullying behaviour	1. Developing listening skills
2. Students making agreed rules for acceptable behaviour	2. Promoting empathy
3. Promoting positive bystander behaviour	3. Saying 'no' to unfair demands
4. How one can respond if bullied	4. Expressing emotions and feelings appropriately

Figure 1. Examples of themes and content for lessons.

The methodology of the school-based bullying program is based on:

- Active involvement of students;
- Changing the attitudes of school staff;
- Improving the social environment;

- Raising awareness amongst parents

The program included:

- Forming a school committee (composed of a social worker, a nurse, a member from the management) in each school;
- Conducting training workshops with the school committees to build their capacities in carrying out the intervention program and increase their awareness of the nature and cycle of bullying, the actions to counter bullying and the different methods that can be used to deal with various cases of bullying within their respective schools;
- Requesting each school to develop an implementation plan which includes selecting the classes/students and activities that will be used during the school year.
- By the end of the intervention, schools' committees met to present their progress reports along with all relevant documentations. These reports and documents provided qualitative data.

Two surveys of students were undertaken in samples of schools in the UAE, one in 2016, and another in 2017. Both made use of a common set of questions designed to provide estimates of the prevalence of bullying in the schools, based on self-reports of (i) being bullied and (ii) bullying others. Estimates of the effects of the intervention were derived in the first study from a comparison of results obtained from students who had experienced the intervention and a control group that had not. In the second study comparisons were made between results obtained from schools where students were assessed both before and after the intervention.

METHODS OF ASSESSMENT

The Tools

To assess the prevalence of bullying in the schools a set of items was devised, adapted from those used originally by Rigby and Slee (1991) and translated into Arabic Language.

To assess the prevalence of being bullied, students were asked to say how often the following happened to them (i) I get called names by others (ii) Others make fun of me (iii) I get picked on by others (iv) I get hit and pushed around by others (v) I receive unpleasant messages from other students through my computer/phone/on-line or on social media such as Facebook. To assess the prevalence of bullying others these items were employed: (i) I am part of a group that goes around teasing others (ii) I enjoy upsetting weak people (iii) I like to make others scared of me (iv) I like to get into a fight with someone I can easily beat.

To provide the opportunity for students to furnish information that was more positive about themselves students were also asked to say how often the following was true of themselves: (i) I like to make friends (ii) I enjoy helping others (iii) I share things with others (iv) I like to help people who are being harassed. Each of the three sets of items was provided with four possible response categories (a) Never (b) Once in a while (c) A few times a month (d) A few times a week.

Finally a question was asked about how safe students felt at school. Respondents were asked: How safe do you feel at school? The response categories were (i) I usually feel safe (ii) I feel safe about half the time (iii) I usually don't feel safe (iv) I never feel safe.

In order to produce multi-item scales, scores in response to the relevant items were summed to produce (i) a Victim Scale (ii) a Bully Scale and (iii) a Pro-social Scale. High scores on the scales indicated (i) being bullied relatively often (ii) bullying others relatively often and (iii) engaging in pro-social behaviour relatively. The reliability of each of the measures as assessed using Cronbach alpha was considered acceptable for short multi-item scales. The obtained values were as follows: Victim Scale, 0.78; Bully Scale, 0.67; Pro-social Scale, 0.66.

In the 2017 survey a further question was added. Students were asked to indicate whether they agreed or disagreed with the following statements: (i) The activities were helpful in reducing bullying between students at my school (ii) I learnt some ways to handle bullying when it will happen to me (iii) The activities gave me sufficient knowledge of bullying (iv) The relations with my colleagues improved after doing the exercises. Response categories were: agree strongly, agree, uncertain, disagree, disagree strongly. The items were used to constitute a multi-item scale reflecting the extent to which respondents were positive about the intervention. The reliability of this scale was assessed using Cronbach alpha 0.73. Finally respondents were asked an open-ended question: Do you have any recommendations to improve the activities?

The Samples

Sample 1 consisted of 1,779 students who answered the questionnaire in 2016 prior to any intervention. In this sample there were 841 boys and 938 girls attending grades 6, 7, 8 or 9. They were recruited from 20 schools in the Emirate. Of these ten were exclusively boys' schools; seven were exclusively girls' schools and three were schools attended by both boys and girls. These mixed gender schools were private, non-government schools.

Sample 2 included a set of 1,093 students (577 boys and 516 girls) from 14 schools who had undertaken the intervention and answered a post-intervention questionnaire. In addition there was a set of students (246 boys and 75 girls) from four schools. These students served as a control group in subsequent analyses.

Sample 3 was answered by a new sample of students in 2017. This consisted of 882 boys and 1,386 girls again from grades 6 to 9. In this sample the schools were all single sex government schools: 11 were schools attended by boys, and 13 schools attended by girls. All the students undertook the intervention. Questionnaires were administered to these students before and after the intervention. In some cases, due to absences on the day of the testing, there were minor discrepancies in the numbers of students from whom both pre and post questionnaire results were available (see Table 1 for details).

RESULTS

Estimates of Bullying Prevalence

The estimated prevalence of bullying in the schools was derived from responses of students who completed questionnaires *prior* to any intervention, which is from Sample 1 in 2016 and

Sample 3 in 2017. These samples were not collected on a random basis therefore cannot be regarded as representative. Hence no conclusions can be drawn regarding changes that may have occurred in bullying prevalence over time. Results are given in Table 2 regarding responses to items assessing frequency of reporting being bullied and in Table 3 regarding the frequency of reporting bullying others at school.

Table 1. Completed questionnaires from students in the 2017 study

	Grade 6	Grade 7	Grade 8	Grade 9	Total Sample
Boys					
Pre-test	153 (17.3)	218 (24.7)	313 (35.5)	198 (22.4)	882
Post-test	180 (21.0)	220 (25.6)	272 (31.7)	186 (21.7)	858
Girls					
Pre-test	357 (25.8)	282 (20.3)	431 (31.1)	316 (22.8)	1,386
Post-test	322 (23.6)	307 (22.5)	423 (31.0)	313 (22.9)	1,365

Numbers of questionnaires completed are given in parentheses.

**Table 2. Percentages of students reporting being bullied
'a few times a month or more often'**

Forms of Bullying	Boys		Girls	
	2016	2017	2016	2017
Being picked on	28.1	26.3	20.7	20.5
Called names	32.5	30.2	19.6	23.7
Made fun of	22.2	25.7	14.6	16.8
Hit	15.8	18.4	8.0	12.6
Cyber	12.4	17.4	8.5	10.3

As indicated in Table 2 for both boys and girls the most common form of bullying was non-physical – being called names, picked on and made fun of. Cyber bullying was the least common form. Notably, on each of the five measures boys reported being bullied more often than girls. The results in Table 3 suggest that 'scaring people' is the most frequently employed mode of bullying others among both boys and girls, and that upsetting 'weak' people is the least common. For the most part these results also suggest that boys are more often involved in bullying others. Again it should be noted that it cannot be inferred from these results that bullying prevalence changed between 2016 and 2017.

**Table 3. Percentages of students reporting bullying
others 'a few times a month or more often'**

Forms of Bullying	Boys		Girls	
	2016	2017	2016	2017
Scaring people	17.7	17.4	11.8	16.7
Teasing in a group	12.0	16.4	9.0	10.9
Fighting with weaker students	11.0	12.2	8.6	13.9
Upsetting 'weak' people	7.0	8.3	4.6	6.0

Estimates of the Effects of the Intervention

In the first 2016 survey comparisons were made between the results from students following the intervention and results for a control group that did not receive the intervention but were assessed at the same time. Because the two groups were not matched for either gender or grade level, multiple regression analyses were used to identify the separate effects of the intervention, gender and grade level. The results suggested that the intervention was probably effective in reducing the reported prevalence of being bullied and bullying others (Rigby and Al Falasi, 2017). However, the sample sizes (especially that of the control group) were quite small and the matching of the intervention and control groups with respect to gender and grade arguably less than adequate. A further study was justified to examine this question.

In the 2017 study comparisons were made between the responses of students to questionnaires before the intervention began and approximately 4 months after the intervention had been completed. The results of the comparisons can be considered in three ways, according to (1) changes in student responses to forms of bullying, (2) changes in scale measures of overall bullying and (3) changes in results for individual schools.

1. Changes in Responses to Forms of Bullying

The results in Table 4 indicate consistent reductions in each form of bullying as experienced by girls. The changes for boys are notably smaller and inconsistent in direction. For ‘being hit by others there was a small increase. Again, as indicated in Table 5 there was a consistent reduction among girls in modes of bullying others. With the exception of teasing in groups, for boys bullying behaviour tended to increase.

Table 4. Percentages of students reporting being bullied ‘a few times a month or more often’

Forms of Bullying	Boys		Girls	
	Pre-test	Post-test	Pre-test	Post-test
Being picked on	26.3	25.0	20.5	17.4
Called names	30.2	26.5	23.7	19.2
Made fun of	25.7	23.4	16.8	12.6
Hit	18.4	20.3	12.1	9.5
Cyber	17.4	14.9	10.3	9.0

Table 5. Percentages of students reporting bullying others ‘a few times a month or more often’

Forms of Bullying	Boys		Girls	
	Pre-test	Post-test	Pre-test	Post-test
Scaring people	17.4	19.3	16.8	12.4
Teasing in a group	16.4	11.7	10.9	9.8
Fighting with easily beat	12.2	13.9	13.9	8.6
Upsetting ‘weak’ people	8.3	10.5	6.0	5.5

2. Changes in Scale Measures of Overall Bullying

In order to assess overall changes in bullying behaviour mean scores were compared on the Victim Scale and the Bully Scale before and after the intervention using a t-test for independent samples. As individual scores for boys and girls pre and post-test were not available, the samples were regarded as 'independent' in this analysis.

Table 6. Scale scores for boys and girls, pre and post tests in 2017

	Pre-test			Post-test			t	df	p-value
	Mean	SD	N	Mean	SD	N			
Boys									
Victim Scale	8.79	3.38	767	8.62	3.55	748	0.10	1513	ns
Bully Scale	5.79	2.49	793	5.78	2.59	787	0.08	1578	ns
Girls									
Victim Scale	7.82	3.11	1262	7.38	3.00	1229	3.59	2489	0.001
Bully Scale	5.55	2.31	1274	5.25	2.11	1257	3.41	2529	0.001

As indicated in Table 6 differences were not significant for boys, but were highly significant for girls on both measures ($p < 0.001$). For girls but not for boys the intervention proved to be effective in reducing bullying.

3. Changes for Schools

Changes in mean scores for schools on the Victim and the Bully Scale before and after the intervention were computed separately for boys and girls. As indicated in Figure 2a reductions were reported in relation to being bullied in 7 of the 11 schools for boys and for girls, a large majority, 13 of the 14 schools.

Figure 2a. (Continued)

Figure 2a. Percentages changes in mean scores on the Victim Scale for respondents attending schools in the United Arab Emirates between pre and post testing.

Changes in mean scores on the Bully Scale were more positive for girls for whom 11 of the 14 schools showed a decrease; among boys only four of the 11 schools showed a decrease in bullying others (see Figure 2b).

Overall, it is clear from the Figures 2a and 2b that there was wide variation between schools regarding the impact of the intervention. This was true for both boys’ and girls’ schools.

Figure 2b. (Continued)

Figure 2b. Percentage changes in mean scores on the Bully Scale for respondents attending schools in the United Arab Emirates between pre and post testing.

How Safe Did Students Feel at School?

In the context of bullying at school students in both studies indicated how safe or unsafe they felt at school. Results were drawn from responses made by students prior to any intervention in 2016 and 2017. Overall, approximately one in six students indicated that usually they did not feel safe or never felt safe at school. This comprised 16.9% of all boys in 2016 and 18.7% in 2017. The corresponding figures for girls were 14.6% in 2016 and 14.4% in 2017. These figures suggest that boys feel less safe at school than do girls.

Did Students Feel Safer After the Intervention?

Contrary to expectations students undertaking the intervention did not feel safer after the intervention. Among boys the percentage of respondents reporting usually or never feeling safe increased from 18.7% to 23.2%. Among girls there was an increase from 14.4% to 15.5%. In hindsight it seems likely that the awareness of bullying at the school raised by the classroom lessons and activities could have increased concerns about bullying, despite (in the case of girls) a reported reduction in being bullied at school.

Did the Students Report Being More Pro-Social Following the Intervention?

Results on the Pro-Social scale following the intervention scale pre and post intervention indicate that there was a reduction in the tendency to report acting pro-socially for both boys and girls. For boys the mean Pro-Social score reduced from 11.72 to 11.40. For girls the

reduction was from 12.48 to 12.15. By t-test both of these results indicated a significant reduction in reported pro-social behaviour at the .05 level. This outcome may appear paradoxical. However, it seems likely that discussions of interpersonal behaviour in classes resulted in students being more realistic in their reporting of their behaviour and less inclined to report in a socially desirable manner (See Fisher, & Katz, 2000).

Evaluations of the Intervention by Students

Responses to questions seeking student views of the effectiveness of the intervention were generally positive (See Figure 3).

A majority of boys and girls saw the intervention as positive in each of the four ways, and especially in improving student relationships. Girls, however, were more positive in their appraisals. The differences between the responses of boys and girls were significant regarding (i) gaining more knowledge about bullying with a higher percentage of girls agreeing with this and (ii) personally handling bullying better.

Comments provided by students about the intervention were in nearly all cases positive.

Figure 3. Percentages of boys and girls evaluating the intervention as positive in different ways.

Evaluative Comments from Students

In illustrating the comments made by students the following notation is employed. The letter 'b' is used to signify boy; 'g' to signify girl. The number following is the grade level.

In general students commended of the schools' initiative in providing the program.

- It is very good and very beautiful (b, 9)
- Excellent. (b, 6)
- Excellent and good (b, 7)

- Beautiful thing (b, 6)
- All activities are beneficial (g, 9)
- Thank God, I am happy with everything. My school is beautiful and great (g, 9)
- They provided good activities (b, 9)
- I enjoyed my time (b, 7)
- It is beneficial because it has taught me to build friendships. (b, 9)
- Apply to all schools (g, 8)
- I like the activities that were implemented (b,7)
- Student collaboration and support for teachers (b, 6)

There were three students who indicated that they did not approve of the intervention (Reasons were not given).

Some students made specific suggestions for improvements:

- I suggest that they increase the number of activities to cap bullying (g, 9)
- Do these activities once a week (g, 7)
- Increase the sessions of activities to face bullying and respect (g, 9)
- Increasing the activities because there are students who do not respect each other, so suggestions should be put to improve this thing (g, 9)
- Increase the number [of activities] and make them for all categories and levels of students (g, 9).
- Provide beneficial activities to improve morals (g, 9)
- The skill-based activities reinforced the knowledge of students (g, 9)
- To have every day a session for development or activities (g, 7)
- Add fun activities (g, 9)
- Improve the school and increase morals (b, 7)
- The activities could also be done 'at home' (b, 6)
- More direct instruction such as lectures (g, 6 and g, 7)

Some students indicated that more awareness of bullying should be encouraged:

- Add an awareness session per week (g, 8)
- More awareness campaigns (b, 8)
- Awareness campaigns about bullying (g, 6)
- Build awareness programs (g, 8)
- More awareness sessions to increase knowledge (g, 6)

A strong desire was expressed by some students for the school to address the problem of bullying (and also anti-social behaviour generally) in various ways:

- Dismiss noisy students from the school (b, 7)
- Dismiss the student who creates a problem in school (b, 7)

- Dismiss the noisy students so that the school can become at a high level (b, 7)
- Put rules and punishments, motivate the students by prizes and appreciate them for their behaviour (g, 9)
- Encourage students to do good deeds. (g, 9)
- Expel all bullies (sic) (b, 9)
- More strict rules about bullying (g, 8)
- More student supervision (g, 8)
- Put in interventions for bullying (g, 6)
- Assign teachers in the corridors (m, 9)

Some students felt that particular attention should be paid to what students could contribute in countering bullying:

- Give attention to children with special needs (g, 6)
- Listen to students' complaints (g, 8)
- More student support (g, 9)
- Gather students' opinions (g, 7)
- Focus on the activities that students like or prefer (g, 9)

Finally, specific suggestions were made on what could be done to improve the lessons employed in addressing bullying in the school.

- Debate and discuss issues (g, 6)
- Show videos about school bullying (g, 9)
- Make plays about bullying (g, 6)
- Put books about bullying in the school library (g, 8)
- Do sessions about self-defence (b, 9)
- Assess the student who got bullied (b, 8)
- Give instruction through school broadcasts (g, 8).

DISCUSSION

The two surveys reported in this chapter confirm earlier findings that bullying in schools in the UAE constitute a serious problem (Kazarian,& Ammar, 2013; Zych et al., 2017), as is the case in many other countries (Modescki et al., 2014) The reported prevalence in UAE schools varied according to the kind of bullying being reported, with name-calling reported as occurring at least monthly by one student in four; being physically bullied by around one child in eight; and being cyber bullied by slightly fewer students. Approximately one student in ten reported that they never felt safe from being bullied.

Unlike previous studies conducted in the UAE, this study provides detailed evidence relating to the effects of an intervention designed to decrease the prevalence of bullying through

the use of classroom instruction and activities. Significant reductions in reported bullying were found specifically for girls, with respect to being bullied at school and also bullying others. Although reductions in bullying prevalence related to the intervention were found for some bullying behaviours in some boys' schools, overall the intervention did not prove to be effective for boys.

The question naturally arises as to why the intervention was generally successful with girls but not with boys. Previous studies on gender differences on the effectiveness of interventions undertaken in different countries have produced conflicting results. In one of the earliest interventions undertaken in schools in Norway the results were more positive for girls (Olweus 2004). It was reported that girls were more receptive to anti-bullying initiatives. By contrast following an intervention reported in England, it was reported that the reductions were more positive and sustained for boys (Smith et al., 2003), Smith et al., commented that bullying by girls is more difficult to tackle. Although there have been a large number of interventions evaluated in many countries (see Ttofi and Farrington, 2011) few have reported on gender differences in the effectiveness of the intervention.

It may be surmised that the nature of the intervention could play a part in explaining gender differences. The intervention employed in this study focussed strongly on student feelings and social skills, rather than the threat of using sanctions or punishment to address the problem. A further factor concerns what is thought appropriate in a given community in interacting with others, especially in the use of force to achieve dominance. An examination of cultural differences between communities may throw some light on aggressive behaviour. In an Arab culture, such as the Emirati culture, bullying in schools can be a sensitive issue to report to the school teachers or administrators. The victims may feel embarrassed to disclose the bullying incidents or report it to anyone. In addition, culturally, parents may encourage their children to respond with violence, thus, making it even more problematic.

It should nevertheless be noted that there were some boys' schools in which the intervention appears to have had the effect of reducing bullying. Two explanations are worth considering. One is the skill employed in delivering the intervention program – a challenging task for some teachers, especially (as some teachers reported) in gaining the cooperation of older students in the activities. It is possible that female teachers in schools for girls are generally more able relate to girls over matters concerned promoting empathy towards others than is the case for male teachers working with boys (Mestre et al., 2009). A further consideration is the classroom climate and school culture which could in some places be highly supportive and in some places not so supportive of such work (Yoneyama and Rigby, 2006).

It should also be understood that the intervention undertaken in this study focussed on one aspect only of the work considered desirable in addressing bullying. Especially, at this stage there has been no evaluation of what could be achieved in schools in the UAE in reducing bullying through the way interventions are carried out in cases of bullying. It is generally held that alternative methods can be used depending on the nature of the bullying, for example whether it is carried out by groups or by individuals and whether it includes violent physical behaviour or covert verbal harassment (Rigby, 2011).

Contrary to expectations the intervention employed in this study did not result in an increase in reported safety at school or in an increase in reported pro-social behaviour for neither boys nor girls. Given the reduction in reported bullying among girls one might have expected girls, at least, to report feeling more safe and acting more pro-socially. It seems probable however that the focus on bullying in the lessons could have resulted in some students

feeling alarmed by the information that was presented. A reduction in feeling unsafe may occur only in the long run after it becomes more apparent that the threat of being bullied has reduced. The lowering of reported pro-social behaviour could have been a result of the lessons producing a greater sense of realism among students about how in fact they behave and lessened any tendency to respond in a socially desirable way. In further studies it could be useful to ask students to indicate how they saw other students behaving at their school.

An encouraging outcome of the intervention in the schools was the positive way in which students appraised the school's initiative in addressing bullying. This suggests that the students on the whole recognised the problem of bullying at their school and welcomed the steps taken by the school to reduce it. Feedback from staff members attested to the value they saw in the enterprise and support for its continuation.

CONCLUSION

Recent research has confirmed that bullying behaviour in schools in the UAE constitutes a social problem, as is the case in other countries. Our findings provide baseline data for the Education Authorities in the UAE to act on, helping decision makers to develop interventions to tackle this issue and support the victims of bullying. It is evident from this study that the use of content as part of the school curriculum to promote social skills and counter bullying can be effective in reducing bullying, at least among girls and also in some schools attended by boys. This approach was strongly supported by most students. Although schools have student misconduct policies and discipline, our data indicate that student bullying is still occurring, creating fears among students and their parents, as well as causing concern among educators and administrators. Further studies are still needed to identify the effects of bullying on the mental health and academic performance of students - and especially to determine what further approaches can be employed in reducing the problem, for example in working more effectively with cases of bullying and working closely with families.

WHAT'S NEXT?

To build on current efforts to reduce prevalence of bullying in schools in the UAE, it is recommended that work should be undertaken in ensuring that all other aspects of the school environment are improved making the schools healthier, safer and more enjoyable to students.

There exists no comprehensive integrated strategies in schools in the UAE on how to promote a safe, healthy and enabling environment. Hence, the development of an integrated model culturally suitable for implementation among schools in the UAE will need to be developed based on the different international successful experiences. The strategies can particularly work on enhancing the school climate and culture, student conduct, social, emotional and character development and will include, but are not limited to:

- Engage parents, families and communities- by providing schools with a deeper understanding of parental engagement and to support the schools' efforts in building full partnerships with parents to enhance student success;

- Increase student engagement and increase the likelihood of participation in extra-curricular activities- by creating opportunities for students to assess school needs, envision and lead improvement projects, and advise school administration to create positive school change;
- Reduce the incidence of violence and bullying;
- Promote mental health- by increasing the awareness of school staff about student social-emotional wellness, factors, symptoms and implications of mental health concerns in a classroom setting, and provide specific skill-based techniques for classroom use;
- Enhance school management and leadership style by harmonizing the relations between staff from mixed nationalities, and increasing their job satisfaction.

ACKNOWLEDGMENTS

First, we sincerely thank the Supreme Council for Motherhood and Childhood for their support in conducting the study. Second, we thank the Education authorities in the UAE: The Ministry of Education and Abu Dhabi Education Council for providing access to schools and facilitating carrying out the training and assessments. Third we are grateful for the contributions of as the School Health Department at the Ministry of Health and Prevention, and SEHA ambulatory health services during the training workshops to school committees. Fourth, we thank the school administration, school staff, parents and students that have participated.

Chapter 125

HOMOPHOBIC AND SEXUAL MINORITY BULLYING: RESEARCH, EDUCATION AND THE FUTURE

James O'Higgins Norman and Mairéad Foody

Homophobic bullying is a 'moral outrage, a grave violation of human rights and a public health crisis...' UN Secretary General, Ban Ki-moon

Bullying undermines the United Nations (UN) Convention on the Rights of the Child and the current United Nations Sustainable Development Goals (SDGs). Both of these important documents, despite being published several years apart, set a specific agenda for the reduction in violence against, and discrimination of, children and teenagers. Bullying falls directly within this remit. In this sense, bullying of any individual because of their race, religion, gender, sexual orientation, or perceived difference is considered a significant violation of human rights and a public health concern.

According to the United Nations World Report on Violence against Children (2006), sexual and gender-based bullying is a significant concern for educational institutions internationally.¹ In this sense, individuals with sexual orientations, identities or expressions of gender that are perceived to be alternative to the norm are at increased risk of victimisation in a school setting. Tackling this specific form of discrimination is thus a public health concern of great urgency. In 2012, the United Nations Educational, Scientific and Cultural Organization (UNESCO) prepared a report reviewing up-to date literature on homophobic bullying. This report recognised the scale of the problem in relation to educational institutions and the need to tackle it head on to reach their goals of achieving education for all and stopping school violence². More recently, the prevention of homophobic/sexual minority bullying falls under the remit of the Sustainable Development Goals set out by the UN, specifically, Goals 4 and 5. Goal 4 aims to ensure inclusivity and the equitable quality education and the promotion of lifelong learning opportunities for all. The objective is to improve both the school environment and access to

schooling for all individuals, especially lesbian, gay, bisexual, transgender and questioning (LGBTQ+) youth. This goal will go a long way to ensuring a culture of peace and non-violence in our schools and digital environments. Goal 5 aims to *achieve gender equality and empower all women and girls*. This sets an agenda to better empower young women and educate young men to achieve their goals regardless of gender and/or sexual identity.

The current chapter is particularly concerned with the bullying of sexual minority children and teenagers within school systems. While we recognise that bullying can happen anywhere, including online, schools continue to be significant sites of harassment for LGBTQ+ youth.³ While previous research in the area has highlighted important issues regarding prevalence and consequences, this chapter attempts to synthesise all available research and provide a timeline of how the literature arrived to where it is today. This is an important feat when we consider the changing face of policy, legislation and freedoms for this group internationally. Investigations of sexual minority youth are imperative if we are to adequately track our progress in creating societies free from discrimination. We will begin the chapter by considering how homophobic bullying is conceptualised in research and its relation to privilege and dominance in schools and society.

SEXUAL MINORITY BULLYING, PREVALENCE AND MENTAL HEALTH

While the term homophobic bullying has its use in particular contexts concerned with people who identify as same-sex attracted it has recently been left aside in favour of the term 'sexual minority bullying' and the term 'sexual minority youth' refers to students who have non-normative sexual orientation and/or identity. These individuals may identify as gay, lesbian, bisexual and/or transgender.⁴ Regardless of the label, the meaning refers to the repeated, intentional abuse (verbal or other) of an individual who displays or is perceived to display sexual or gender identity counter to normative behaviours and identities. In the nature of the specific term bullying, a power hierarchy is always present where the bully is indefinitely more powerful than the victim. What is known about school experiences for these individuals is discouraging and they are reported to be at increased risk of victimisation by peers compared to students identifying as heterosexual.^{5;6;7} There are many influences on an individual's sexuality including explicit and implicit rules imposed by society.⁸ It has been argued that human sexuality can be understood in terms of a continuum with heterosexuality at one end

point and homosexuality at the other and varying realities between them.⁹ Not only might there be a continuum of sexuality, but it might also have the element of being fluid. That is, depending on our education, development, emotions, needs for intimacy, etc., as the years go on, our sexual preference may move along the continuum. However, schools as agents of society tend to reproduce dominant ideologies which means that where sexuality is concerned heteronormativity is the key stone of normative behaviour in schools. Homophobic bullying is therefore understood as a symptom of difference from normative expressions of sexuality in society.

Prevalence rates for victimisation of this group varies from country to country and by the research methods used. The National School Climate Survey in the United States assessed school experiences of over 10,000 lesbian, gay, bisexual, transgender and queer 13-21 year olds. This large school study found that 48.6% of the sample had been victimised online, 27% has been physically harassed and nearly 60% had been sexually harassed.¹⁰ Nearly all of the sample (96%) reported that they had heard other students use homophobic remarks about them. Increased risk of victimisation for LGBTQ+ students have also been reported in both Ireland and Northern Ireland^{11,12}.

There is overwhelming evidence to support the fact that sexual minority youth report more short and long-term health and academic problems compared to their heterosexual comparisons.¹³ It is important to note that these differences are explained by the adversary these individuals experience as a result of the fear of prejudice that can be attached to their identity in society.¹⁴ In this sense it is feelings of loneliness, isolation and fear that may have a negative impact on an LGBTQ+ individual's school life, mental and physical health. The chronic stress of experiencing discrimination, bullying or any form of prejudice for something inherently related to your sense of self, undoubtedly can have clinical implications.

In terms of mental health, increased levels of anxiety,^{15,16} depression,¹⁷ suicidal ideation¹⁸ and substance abuse¹⁹ have been reported for these individuals. A recent study in Ireland, reported a sevenfold increase in the odds of self-injury or suicide attempt for sexual minority

youth compared to heterosexual peers of the same age (19-24 years).²⁰ This risk factor for increased mental health difficulties also relates to individuals who do not necessarily report as sexual minorities but are perceived to be so and victimised for such. Swearer, Turner, Givens and Polack (2008) found that boys verbally bullied by being called 'gay' were more likely to experience psychosocial stress, regardless of their actual sexual orientation.²¹ On the other hand, individuals who were questioning their sexual orientation reported more bullying and mental health issues compared to heterosexual or LGBTQ+ students.²² In addition, sexual minority males showed increased risk of injury with a weapon and truancy as a result of safety concerns in the United States due to peer victimisation.²³ Peer victimization may also lead to school truancy and reduced academic achievement for LGBTQ+ students.²⁴

HOMOPHOBIC BULLYING AND HETEROSEXUAL PRIVILEGE

Hamarus and Kaikkonen (2008) argue that only acts that conform to a particular definition of bullying are identified and labelled as bullying thus excluding whole aspects of conflict and aggression that may also occur.²⁵ Olweus (1993) suggests that "a person is bullied when he or she is exposed, repeatedly and over time, to negative actions on the part of one or more other persons, and he or she has difficulty defending himself or herself."²⁶ Use of Olweus' definition and related self-report questionnaire on bullying has been extensive in international research. However, this approach has been critiqued from the point of view that it does not account for nuances in different cultural meanings and terminology associated with the concept of bullying nor does Olweus' approach allow for an examination of social structures that preference what is considered to be normative in societies and in schools. The criticism meted out by Cullingford and Brown (1995) and Lee (2006) towards the approach recommended by Olweus (1993) argues that his approach could possibly be regarded as value-laden and reflects the power of the researcher to define bullying and related behaviours are excluded.^{27,28} This has implications for schools. As agents of society, schools will often reflect dominant social ideologies that privilege one group over another. The core challenge here for schools is how to develop workable definitions of bullying that focus as much on the implications of wider social structures and not so much on those who are perceived to be different.

In terms of current research on homophobic bullying it is frequently framed within existing definitions of bullying as addendum that includes reference to “words or actions associated with sexuality.” For example, Douglas, Warwick, Kemp and Whitty (1997) defined homophobic bullying as “taking place where general bullying behaviours such as verbal and physical abuse and intimidation is accompanied by or consists of the use of terms such as gay, lesbian, queer or lezzie by perpetrators.”²⁹ The fact that the definition is written in this way reinforces the difficulty surrounding homophobic bullying and conceptualising it as one distinct phenomenon. It is complex because it combines both homophobia and bullying into one issue, when in fact they are two very distinct issues. Redman (2000) argues that use of the term homophobia implies a “psychological fear and loathing of homosexuality”³⁰, but as Espelage and Swearer (2008) recognise, victimisation as a result of homophobia, is not confined to lesbian, gay, bisexual or transgender identified individuals³¹. In other words, when homophobic terms are used as pejoratives in schools they are not always intended to contribute to the victimisation of pupils who may identify as LGBTQ+. In many cases they are used as a way to police the boundaries of what is considered normal and to support the privilege of a heteronormative school environment. In that context we note findings from studies conducted in primary schools in the UK³² and in the USA³³ which show that children use the terminology associated with homophobia to target others who are different in dress, language, style and personality, but do not necessarily have a fear of or loathing of homosexuality *per se*. In fact, Payne and Smith (2013) concluded that the majority of peer to peer conflict ultimately supports some form of heteronormative privilege in schools. As stated above, schools play a very significant role in reproducing dominant ideologies in society and despite emerging changes in attitudes heteronormative culture still dominates society and as such expressions of this culture will be celebrated and validated in schools in the most unconscious fashion.

THE SCHOOL ENVIRONMENT

The implication of this heteronormative orientation by schools is that we equally need to be able to recognise behaviour as bullying, whilst also being aware of the power of a normative environment to produce bullying against those who are perceived as different. In other words, homophobic bullying can be understood as a phenomenon that underpins the heteronormative ethos of the school environment. The negative language often associated with homophobic bullying is used to describe something that cannot be separated from the sexual and gender connotations they carry as in the case of heteronormative cultures.³⁴ In many schools, children

are only taught about heterosexuality and a great silence exists in relation to sexual diversity i.e., expressions of sexuality other than heterosexuality. As DePalma and Jennett (2010) suggest, this is an example of how schools reinforce the view sometimes held within sections of wider society- that sexualities other than heterosexuality are at least unacceptable, if not deviant. If children use homophobic language, and it is accompanied by or coupled with other negative behaviours, then this is a very specific form of bullying which is directed at individuals, or groups of individuals for a variety of reasons; including because of the perception that they are different.

There is an abundance of literature documenting the ill-effects of involvement in bullying for our young people. Yet, schools in general have been slow to develop specific policies and support for these individuals. One important element in this equation is school climate and research is beginning to document the importance of a positive one in preventing and intervening with bullying. School climate refers to the quality and character of school life and takes into account the atmosphere and behaviours of the school.³⁵ In one large-scale meta-analysis, Marx and Hensman Kettrey (2016) found that schools who engaged with organisations to encourage dialogue between sexual minority and heterosexual youth had significantly less students reporting victimisation and a more positive general school climate overall.³⁶ On the contrary, bullied LGBTQ+ youth were less likely to report aggressive behaviour and suicidal behaviours when they had one adult they felt connected to in the school environment.^{37,38}

It is no surprise that students perceived as being different due to their gender or sexual identity are more likely to be the target of bullying.^{39,40} What is surprising is that schools have not always been productive with preventative policies and the same barriers to education that faced our children decades ago are still in place today. It is important that we understand homophobic bullying both as an individual and a sociological problem. Such a shift in how we understand homophobic bullying involves a recognition that while certain individuals are more likely to bully due to social and/or emotional deficits, the social context in which they live and study can also contribute towards a school climate where bullying is more acceptable. Young people are rarely bullied in schools because they are perceived to be the same as everyone else. Rather they are often bullied because they stand out in their environment as being different from their peers. This reality points to the need for schools to promote diversity as a “normal” part of life and to develop policies and structures that challenge, limit and reshape heteronormative cultures. The research shows that where young people are provided with an

opportunity to reflect on difference as a positive aspect of life, levels of sexual minority bullying and other forms of discrimination decrease.^{41,42,43,44,45,46,47}

THE SITUATION IN IRELAND

The first study specifically on homophobic bullying in Ireland was conducted by O'Higgins Norman (2008, 2009). This research highlighted the difficulties facing LGBTQ+ individuals, their teachers and school systems in tackling bullying and discrimination in what was previously a state highly influenced by the teachings of the Roman Catholic Church. Almost a decade later, some of these challenges still exist in Irish schools. Dramatic legislative change in Ireland in recent years has impacted on the lives of LGBTQ+ individuals, not least the extension in 2015 of the right to marry same-sex partners. Yet, despite this significant change, young people in Ireland still report negative experiences and 47% of young LGBTQ+ people still feel there is a lack of acceptance and understanding in Irish society.⁴⁸ While legislative change marks a formal acceptance of same-sex partners, it can take years before this trickles down to all sections of society and there is a real sense of acceptance at the community level. Kitching (2013) identifies the low response by parents to proposed changes in school patronage in Ireland to the continuance of what Inglis (2007) describes as an unquestioned Catholic habitus⁴⁹ which intersects with, and is expressed in lived ways through the politics of class and race.⁵⁰ From Foucault's perspective it stands to reason that Irish society will not be able to free itself from its traditional habitus except at a considerable cost "nothing less than a transgression of laws, a lifting of prohibitions... a reinstating of pleasure within reality and a whole new economy in the mechanisms of power will be required."⁵¹ The ultimate outcome of the marriage equality referendum in Ireland in May 2015 revealed that while the majority of people in Ireland may still operate many aspects of their life through a Catholic habitus they are also capable of setting it aside and making choices that are not necessarily reflective of that habitus to which they adhere to in other parts of their lives. This parallels with the problems facing our schools who may in effect have appropriate policies and anti-bullying initiatives in place, yet display a heteronormative ethos counter to these efforts. For example, on one hand,

a school's anti-bullying policy may state that homophobic bullying is not tolerated, while on the other hand, it may unwittingly not include same-sex relationships in various syllabi.

CONCLUSION

While Ireland may appear to be taking positive steps in promoting equal rights of LGBTQ+ individuals at the policy level, the extent to which young people are experiencing this 'acceptance' in schools has yet to be established. For many teenagers, marriage is seen as something in the future and not entirely relevant to their life stage. What may be conducive to promoting positive mental health in our young people (LGBTQ+ and others) may need to involve their direct environment such as schools and peer to peer interactions. Positive school climates, where differences are not just tolerated or 'allowed' but embraced are required along with communities which promote diversity at all levels. Various systems in society (such as schools) will need to shift perspective and recognise that all interventions (e.g., anti-bullying programmes) will be limited if implemented from a heteronormative view point. We need to develop our view of the individual who is bullied as one who doesn't fit to standard gender or sexual norms for example, to considering how our norms actually allow for diversity in the first place.

Until very recently, there has often been a refusal by Western societies to listen to people who identify as LGBTQ+ and their experiences of not identifying with heteronormative behaviours and cultures. For a long time both civil and religious society have treated any attempt to even question the predominant assumptions about sexuality (and homosexuality) with a prohibiting silence, which inhibits any further questioning. This silence has been maintained and carefully controlled historically through a variety of processes in wider society. A primary function of schools, like other social institutions, is the reproduction of the dominant social ideology. Schools legitimate and sustain cultural practices. While our current understanding of bullying and homophobic bullying is incomplete,⁵² the daily worlds of our schools continue to teach a script for what is considered to be appropriate gender and sexual behaviour during adolescence and later on in adulthood.

Chapter 126

INDIVIDUAL LEVEL OF PREDICTORS OF FACE TO FACE BULLYING: THE FINDINGS OF A TWO-WAVE LONGITUDINAL STUDY

Fatih Bayraktar^{*}, PhD

Department of Psychology, Faculty of Arts and Science
Eastern Mediterranean University, Famagusta, North Cyprus

ABSTRACT

Although the research on bullying is almost in its 50th year, still there is need for longitudinal studies. Therefore, the main purpose of this research was to examine the individual-level predictors of face to face bullying among a Turkish Cypriot adolescent sample in two waves (time interval: one year). A total of 268 adolescents (143 females, 124 males, 1 missing; Mean age = 14.7, SD = .52) have been recruited from public schools which settled in four different districts of Northern Cyprus. Age, gender, media use, perceived popularity vs unpopularity, prosocial and antisocial behaviors (both in real life and cyberspace) were analyzed as predictors in Time 1. Face to face bullying in Time 2 was predicted by face to face bullying, perceived unpopularity, age and using chat rooms in Time 1 positively. On the other hand gender (1 = female, 2 = male), helping others in cyberspace, perceived popularity and using blogs in Time 1 predicted face to face bullying negatively in Time 2. All coefficients were significant at $p < .05$. The results indicated that face to face bullying had a stability; older ones and females perpetrated bullying more; perceived unpopularity and using chat rooms were risks for future bullying. The findings will be discussed in both theoretical and practical implications.

Keywords: school, face to face bullying, adolescents, longitudinal study, individual factors

1. INTRODUCTION

Bullying is an aggressive behavior which is repeated, targeting a weaker victim or victims (which indicates a power imbalance physically, psychologically and/or socially) and intending to harm. When the empirical research about bullying started in the late 1960s and early 1970s (see Heinemann, 1972; Olweus, 1973) the main context was focused on the school. Therefore *school bullying* term is often used instead of peer bullying (ex: Evans, Fraser, & Cotter, 2014; Sharp, & Smith, 2002; Wang, Iannotti, & Nansel, 2009; Ybarra, Diener-West, & Leaf, 2007). Olweus (1993) arrayed a series of factors which were related with school bullying: the size of the school and classrooms, monitoring during break times, the rate of competition in the school, discipline style of adults (i.e., authoritative vs authoritarian) and group dynamics at school. Following studies consistently confirmed that school related factors such as monitoring by teacher, teacher support, classroom management skills of teachers, school bonding and psychological climate of the school was strongly related with bullying (Demaray & Malecki, 2003; Limber, Olweus, Wang, Masiello, & Breivik, 2018; Parault, Davis, & Pellegrini, 2007; Sprott, Jenkins, & Doob, 2005; Welsh, 2000). It is clear that school as a main socialization context during childhood and adolescence includes both opportunities and risks for social-emotional development and bullying is one of the major risks.

Although there is an enormous literature about school bullying, most of the research is cross sectional (see Kljakovic and Hunt's (2016) meta-analysis study for longitudinal research on bullying and victimization, also see Alvarez-Garcia, Garcia, and Nunez's (2015) review on school bullying). In those cases (i.e., cross sectional studies) it is difficult to talk about risks and protective factors which can be analyzed through longitudinal or experimental studies. Therefore, the main aim of this research was to examine the individual-level predictors of face to face bullying among a Turkish Cypriot adolescent sample in two waves (time interval: one year). The reason to choose individual level factors (but not school related factors) was the empirical proof which indicated that these factors were the strongest predictors of aggressive behaviors (ex: Bayraktar, 2012; Khoury-Kassabri, Benbenishty, Avi Astor, & Zeira; 2004; Lee, 2000; Welsh, Greene, & Jenkins, 1999; Zych, Farrington, & Ttofi, in press) beyond the school related factors. Also, adolescence was suggested as a risky period of life compared to other developmental stages (see Troop-Gordon's (2017) review article for peer victimization in adolescence). Age, gender, media use, perceived popularity vs unpopularity, prosocial and antisocial behaviors (both in real life and cyberspace) were analyzed as predictors in Time 1. The variables were selected to explain the demographical links (i.e., age and gender), to contribute to the literature with longitudinal findings (i.e., perceived popularity vs unpopularity, prosocial and antisocial behaviors in the real life) and to present new links (i.e., media use, prosocial and antisocial behaviors in cyberspace) to the best of our knowledge. Below the literature which shows the links between those variables and bullying will be reviewed briefly.

1.1. Age and Bullying

Although some studies argue that bullying is a stable behavior which continues through the life course in different and more complex forms (Kaukiainen, Björkqvist, Österman, & Lagerspetz, 1996; Scheithauer, Hayer, Petermann, & Jugert, 2006), there are also some research

findings which indicated that bullying decreases with age (ex: Eslea & Rees, 2001; Rigby, 1996). From a life span developmental perspective, none of the behaviors can be counted as stable throughout the life because of flexibility characteristic except the negative contextual factors are not be able to decreased or eliminated. Therefore as well known the prevalence of bullying can be decreased with prevention and intervention programs which aim to improve the contextual conditions (i.e., home and school related factors). However, in every case the age (i.e., developmental stage or grade) of the bully and the victim must be counted (Albayrak, Yıldız, & Erol, 2016).

It is expected that patterns of bullying (if it continues) will change over time and older students will show more indirect, verbal and manipulative strategies to bully others because of developing cognitive and social skills (Henington, Hughes, Cavell, Thompson, 1998; Scheithauer et al., 2006). Although there is not a certain peak of bullying behaviors, adolescents can show a wider behavioral spectrum compared to children. Therefore the sample of the current study included adolescents. Also the age was used as an independent variable to predict (or not to predict) bullying. This possible link can show whether the age is a risk or not. Because bullying was measured as a sum score of different forms, it is hypothesized that age will predict bullying positively (Hypothesis 1).

1.2. Gender and Bullying

There is a robust literature which indicated that males are more at risk as perpetrators (ex: Berthold & Hoover, 2000; Spriggs, Iannotti, Nansel & Haynie, 2007). Male tendency to bullying and in general to aggressive/violent behaviors can be explained biologically (i.e., higher levels of testosterone) or via socialization processes (e.g., Bettencourt, & Miller, 1996; Windle & Windle, 1995). Therefore the first studies in bullying focused on males as usual suspects of aggressive behaviors, the subsequent literature clearly indicated that bullying was not only typical for males but also for females. Yet when the sub-types of bullying are counted a lot of studies showed that both males and females are tended to be bullies. However when direct and indirect forms of bullying are considered, a lot of research showed gender differences; males were found to be more at risk for direct forms while females were showing more indirect forms (ex: Carbone-Lopez, Esbensen, & Brick, 2010; Putallaz et al., 2007).

In the current study, similar to the *age*, gender was used as a predictor of bullying in long term. Because the bullying measure included both overt and relational forms (see Methods) instead of hypothesis a research question was asked: “Does being male or female increase the risk of bullying in time?”

1.3. Media Use and Bullying

Media use may shape the perceptions about the phenomena and may have an effect on human actions (Kuntsche, 2004). There are consistent findings that exposing violence on TV may trigger aggressive thoughts and under frustration increase the risk to show aggression (e.g., Bandura, 1994; Hughes & Hasbrouck, 1996). A lot of research indicated similar effects of playing violent video games (e.g., Dill & Dill, 1998; Sherry, 2001). When contemporary world

is considered although watching TV or playing video games are not rare among adolescents, new media use (i.e., Information Communication Technologies) are becoming much more popular. This can be explained via the concept of *Electronic Nomads* which was used first by Russell and Holmes (1996) to define the adolescents' ability to adapt digital media platforms and tools. Accordingly a new form of bullying called cyberbullying became a risk factor since 2000s because of increasing internet penetration rates and increased number of smart phone use throughout the world (Nocentini et al., 2010).

In the current study cyberbullying was not measured although there are a lot of empirical findings which indicate an overlap between face to face bullying and cyberbullying (e.g., Ybarra, Diener-West, & Leaf, 2007). The main focus was to find the link between electronic media use and bullying. It was hypothesized that the digital media platforms which may enhance the possibility of cyberbullying (i.e., chat rooms, online games, social media platforms etc.) would also be related with higher face to face bullying rates but not the others (i.e., blogs, personal web sites etc.) (Hypothesis 2).

1.4. Popularity and Bullying

Acceptance (being liked by the peers) and popularity (perceived dominance and visibility in the peer group) are the related but interdependent indicators of social status among students. Although the victimization was consistently found to be associated with being disliked and unpopularity (e.g., De Bruyn, Cillessen, & Wissink, 2010; Prinstein & Cillessen, 2003), the links between bullying and social status are more complex. While some of the bullies were found less liked and popular among the peers, the same bullies were having higher perceived popularity scores (e.g., Farmer, Estell, Bishop, O'Neal, & Cairns, 2003; Vaillancourt, Hymel, & McDougall, 2003). This distinction is based on the difference between socio-metric popularity and perceived popularity (Parkhurst, & Hopmeyer, 1998). Later these dimensions were explained in Cillessen's (2008) *dual-component model of social competence* which stressed that peer acceptance (or socio-metric popularity) and perceived popularity were two components of social competence. The first component was related with being prosocial, cooperative, empathic, and having higher social cognitive abilities. The second component was related with being coercive, forceful, assertive and manipulative. Therefore a bully could have higher scores from one component but having lower scores from the other.

In the current study, popularity was tested as a self-report measure to focus on self-perceptions of the participants. It was suggested that interpersonal and intrapersonal factors were related with each other (e.g., Mayeux, & Cillessen, 2008; Peets, Pöyhönen, Juvonen, & Salmivalli, 2015) and therefore bullying would negatively be related with self-reported popularity (Hypothesis 3).

1.5. Prosocial Behaviors and Bullying

As mentioned above prosocial behaviors were one of the components of social competency and theoretically they are expected to be negatively related with bullying. However some studies indicated that *Machiavellian* bullies were socially competent and had higher perspective

taking and theory of mind abilities compared to typical bullies (e.g., Andreou, 2006; Sutton and Keogh, 2000). This was in line with Davis' (1994) *multidimensional model of dispositional empathy* which stressed that empathy had two main components; cognitive component (i.e., perspective taking) and emotional component (i.e., concerning the others and being sympathetic). In the other words some bullies may use only the cognitive component of empathy but still not being empathetic. Resource Control Theory (Pellegrini, 2008) stress that social status and social dominance are the sources of power and generally gained by either using coercive strategies or prosocial strategies. Although coercive strategies (i.e., threatening, forcing, excluding etc.) are often called anti-social, these are also social dominance strategies and somehow adaptive. On the other hand prosocial behaviors may also benefit the individual via cooperation and allies to enhance the source control. Accordingly Hawley (2003) defined four statuses of source control: using both prosocial and coercive strategies (i.e., bi-strategic controllers); using only coercive strategies, using only prosocial strategies and using none of the strategies Hawley, Little and Pasupathi (2002) found that the ones who gain the source by using both prosocial and coercive strategies were found to be popular and socially dominant. On the other hand the ones who use neither of the strategies were found to be submissive (an indication of victimization). In sum bullies may use prosocial behaviors to get benefit.

In the current study the prosocial behaviors were measured in the real life also in the cyberspace as cyber-prosocial behaviors. Previous research indicated that real life and virtual life behaviors are mostly overlapped (e.g., Bayraktar, & Amca, 2012; Subrahmanyam, Reich, Waechter, et al., 2008; Valkenburg, & Peter, 2007). To the best of our knowledge, there was no study to test the link between cyber-prosocial behaviors and bullying. Therefore instead of hypothesis a research question was written: "Are the face to face and cyber prosocial behaviors correlated with bullying in time?"

1.6. Theoretical Background

Theoretically Bronfenbrenner's (1979) ecological model and Masten's (2006) principle of multi-dimensionality were used. Bronfenbrenner (1979) stated that human development occurs within a series of systems respectively shape the development from more directly to more indirectly. However at the center there are always individual level variables which have the strongest effects over developmental outcomes (See the review of the ecological system analysis by Hong and Espelage, 2012). Similarly Masten's (2006) principle of multi-dimensionality stresses that the researchers must study individual level, proximal and distal factors to understand the risks and protective factors of human development. However, individual level factors are the core variables as risks and protective factors for later developmental outcomes (Ttofi, Bowes, Farrington, & Lösel, 2014; Ttofi, Farrington, Lösel, & Loeber, 2011). Therefore to understand the long term associates of bullying the current study focused on individual level variables.

2. METHODS

2.1. Participants

A total of 268 adolescents (143 females, 124 males, 1 missing; Mean age = 14.7, SD = .52) have been recruited from public schools which settled in four different districts of Northern Cyprus. School system in Northern Cyprus include primary school level (from 1st to 5th years), secondary school system (three years after primary school education) and higher school system (another three years after secondary school). When the first wave of data was collected most of the students were at the second year of secondary school. Therefore when the second wave of the data was collected they were the oldest students in their schools which may increase the probability of the bullying. Public schools were selected to increase the socio-economic representativeness of the sample.

2.2. Measurement Tools

2.2.1. New Media Use

The frequency of use for nine information and communication technologies were asked (1- Never, 5-All of the time). The ICTs were as following; Social Networking Sites (e.g., Myspace, Facebook, Instagram), Chat Programs (e.g., AOL Instant Messenger, Yahoo), Text Messages (through cell phone), Email, Public or Private Chatrooms, Blogging Sites (such as Live journal, MSN Spaces), Online Gaming, Forums (i.e., discussion boards), Video Chat Programs (e.g., Skype).

2.2.2. Face-to-Face Bullying and Prosocial Behavior Scale (Wright, Li, & Shi, 2014)

This scale measured overt and relational bullying with face to face prosocial behaviors (1- Never, 5- Always). In the current study the sum score of overt and relational bullying was used (Sample items: *How often do you leave a peer out of a group because you are mad at him/her?*; *How often do you hit others at your school?*) The Cronbach Alpha for eleven items which measure bullying was .83.

The scale also measured prosocial behaviors (Sample items: *How often do you do something that makes your peers feel happy?*; *How often do you say something nice to your peers?*). The internal consistency of this sub-dimension was found as .79.

2.2.3. Cyberbullying and Cyber-Prosocial Behavior Scale (Wright, & Li, 2012)

This scale measured both cyberbullying and cyber-prosocial behaviors (1- Never, 5- Always). In the current study only the cyber-prosocial behavior dimension was used (Sample items: *How often do you help other peers online or through text messages?*; *How often do you say something nice to other peers online or through text messages?*). Cronbach alpha for four items was found as .79.

2.2.4. Self-Perceptions of Status (Mayeux & Cillessen, 2008)

This questionnaire was designed to measure the self-perceptions of perceived popularity and social preference (1- Almost nobody, 7-Almost everybody). There were two items; *How*

many people in your grade think that you are popular? and *How many people in your grade like you?* Internal consistency between the items was .84.

2.3. Procedure

First the research ethics approval was obtained from Eastern Mediterranean University Department of Psychology Research Ethics Committee. Then the permit to collect the data from the schools was authorized by Ministry of Education. The school administrations and school counselors were informed about the study. The data were collected during lecture hours with the attendance of school counselor and one research assistant to answer the questions. One year later the same schools were revisited and by using the school numbers the students were reached again with the help of the counselors.

Figure 1. The Associations between Individual Level Predictors in Time 1 and Bullying in Time 2 (All coefficient are significant at $p < .05$).

3. RESULTS

3.1. Incidence and Prevalence of Bullying in Time 1 and Time 2

The mean score of bullying increased from 13.48 (SD: 5.12) in Time 1 to 15.77 (SD: 7.64) in Time 2. When 1 Standard Deviation over the mean score was used as a cut-off point the prevalence of bullying was 18.4% in Time 1 and 19.04% in Time 2.

3.2. Longitudinal Associates of Bullying in Time 2

As mentioned above, bullying in Time 2 was used as a dependent variable and age, gender, media use, self-reported perceived popularity vs unpopularity, prosocial behaviors (both in real life and cyberspace) were analyzed as predictors in Time 1 (See Figure 1).

4. DISCUSSION

Although the research on bullying is almost in its 50th year, still there is need for longitudinal studies. Therefore, the main of this research was to examine the individual-level predictors of face to face bullying among a Turkish Cypriot adolescent sample in two waves (time interval: one year). Face to face bullying in Time 2 was predicted by face to face bullying, perceived unpopularity, age and using chat rooms in Time 1 positively. On the other hand gender (1 = female, 2 = male), helping others in cyberspace, perceived popularity and using blogs in Time 1 predicted face to face bullying negatively in Time 2.

The positive association between face to face bullying in Time 1 and Time 2 (which validated Hypothesis 1) indicates that the bullying was stable at least within one year. This was not consistent with the research which found that bullying decreased in time (ex: Eslea & Rees, 2001; Rigby, 1996). As mentioned above this stability can be explained through complicated bullying behaviors (Henington et al., 1998; Kaukiainen et al., 1996; Scheithauer et al., 2006). In the current study bullying was measured as a sum score of overt and relational bullying. It can be expected that more relational (so complicated) bullying behaviors occur in time. This stability was also supported by incidence and prevalence rates of bullying.

The second explanation of positive association between Time 1 and Time 2 face to face bullying can be the status of students within the school. When the data were collected in Time 2 the students were at third year in the secondary school which means that they were the oldest ones at school. Both physical growth and using more complex social cognitive skills compared to younger ones might increase the risk of bullying. Also being older itself can create a kind of hierarchy, inequality and power imbalance (which is one of the main criteria of bullying) among students (e.g., Elgar, Craig, Boyce, Morgan, & Vella-Zarb, 2009; Garandeau, Lee, & Salmivalli, 2014).

In the current research gender (1 = female, 2 = male) predicted face to face bullying in Time 2 negatively. In other words being female increased the risk of bullying in time. This finding can be explained through the measurement of bullying in the current research. As explained above the bullying measure included relational form items and the previous study consistently indicated that females use more indirect forms (ex: Carbone-Lopez, Esbensen, & Brick, 2010; Putallaz et al., 2007). However it is also possible that females use both overt and covert forms of bullying. In an early meta-analysis, it was shown that gender differences in aggression were getting smaller between the years 1978-1981 (Hyde, 1984). This decrease was explained through the gradual disappearance of traditional gender stereotypes which stress the aggressiveness-dominance of maleness and vulnerability-submissiveness of femaleness. It is obvious that when 'gender norms' disappear (ex: in sports or in cyberspace) both males and females might show similar aggressive behaviors. For example some research on cyberbullying indicated that females show more bullying compared to males (e.g., Bauman, 2012; Kowalski

& Limber, 2007). Also in earlier times of life it was found that there was no difference in aggression between males and females (Lansford et al., 2012). This also supports that aggressive behaviors are mainly related with gender socialization and when genders become equalize, males and females start to resemble each other.

Second hypothesis of the current study was that the digital media platforms which might enhance the possibility of cyberbullying (i.e., chat rooms, online games, social media platforms etc.) would also be related with higher face to face bullying rates but not the others (i.e., blogs, personal web sites etc.). This hypothesis was accepted. It was found that using chat rooms was positively associated with face to face bullying in Time 2, on the other hand there was a negative link between using blogs and bullying. These links can be explained through the overlap between cyberbullying and bullying (e.g., Ybarra, Diener-West, & Leaf, 2007). In other words chat rooms can enhance the students to bully others both in cyberspace and trigger face to face bullying in real life. The previous research supported this finding which indicated that chat rooms extend the bullying at schools (e.g., Campbell, 2005; Juvonen, & Gross, 2008; Kowalski, & Limber, 2007). To the best of our knowledge the negative link between using blogs and bullying has not been found in the previous research. On the contrary some studies counted blogs among ICTs which enhance cyberbullying and bullying (e.g., Keith, & Martin, 2005; Menesini, Calussi, & Nocentini, 2012). Therefore this empirical finding can be counted as the first positive connotation for using blogs. However, this link has to be reevaluated by future research.

Hypothesis 3 was also accepted. The findings showed that self-reported popularity was negatively associated with face to face bullying while there was a reverse link between self-reported perceived unpopularity and bullying. Although the literature on popularity-bullying association has been growing since 1990s, still there is confusion. This uncertainty can raise from the domination of *typical* perceptions or definitions about bullies. Typically most of the bullies are perceived as unpopular, cognitively immature, socially incompetent etc. However as mentioned above there is also *allure of a mean friend* (Farmer, et al., 2003; Hawley, Little, & Card, 2007; Vaillancourt, et al., 2003). As stressed before the confusion can be solved when acceptance/ to be liked (i.e., socio-metric popularity) and perceived dominance within the peer group (i.e., perceived popularity) is differentiated. The current findings indicate that the students who bully others more are aware that they are not liked. This shows the link between interpersonal and intrapersonal perceptions (e.g., Mayeux, & Cillessen, 2008; Peets, et al., 2015). Moreover, this self-reported perceived unpopularity was found as a risk in the long term. In other words students who perceive that they are not liked within the peer group because of bullying end in more bullying. One of the possible reasons can be emotion of anger that was not analyzed in the current research. However previous research indicated that anger is one of the basic motives in bullying (e.g., Bosacki, Marini, & Dane, 2006; Gradinger, Strohmeier, & Spiel, 2009). So the future research may take the link between popularity and bullying by taking both motives and the different dimensions of bullying.

Last research question was about the association between cyber/real life prosocial behaviors and bullying. There was not a significant relationship between prosocial behaviors in real life and face to face bullying. However, it was found that cyber-prosocial behaviors in Time 1 were negatively associated with bullying in Time 2. Because there was not an empirical finding in the previous researches which showed the similar link, we may have some suggestions: First, this association might be found because of the overlap between cyberbullying and bullying. Although the current research didn't focus this link, in another

research which used the same data it was found that face to face bullying in Time 1 was significantly correlated with cyberbullying in Time 2 and cyberbullying in Time 1 was again positively correlated with face to face bullying in Time 2 which clearly showed the overlap (Bayraktar, under review). Therefore the negative link between cyber-prosocial behaviors and bullying might be an expected finding when these behaviors were evaluated as the opposite of cyberbullying. Second, when Davis' (1994) multi-dimensional model of dispositional empathy was counted, we may suggest that the students in our sample who bully others more might be using the cognitive component more compared to emotional component. This could result in less prosocial behaviors when the emotional empathy was considered as the core of these behaviors. Third, when Resource Control Theory (Pellegrini, 2008) was counted it seems that the perpetrator students in our sample use more coercive strategies instead of being bi-strategic controllers. This possibility might also explain the negative link between cyber-prosocial behaviors and face-to-face bullying. However, these are all suggestions and must be tested by future research.

4.1. Implications

School is still one of the major socialization contexts for children and adolescents. Therefore all prevention and intervention programs must focus on the risk and protective factors in the school. However, a holistic approach is also needed to take into account the other factors. Aforementioned, maybe the most critical risk and protective factors are the ones at the individual level. Our findings may have some implications at this point.

First, the age (or grade) of the student must always be counted. The current findings indicated that face to face bullying increased in one year interval. When the programs are designed the highest grades within the school may be evaluated at risk for bullying others. Because power is a key word for bullying, using power for prosocial aims (ex: helping the students at lower grades, protecting them against the dangers) can be encouraged especially for those students.

Second, the males must not be the usual suspects of bullying. The adults in the school can be informed about the nature of bullying which is not related with maleness or femaleness but stereotypical gender roles which link power/dominance to masculinity and victimization/submissiveness to femininity. This awareness can catch more bullying cases among females at schools.

Third, using blogs was found as a protective factor against bullying. Using a critical but not an encouraging language about bullying in personal blogs can increase the sensitiveness of other students. Especially those who were victimized can tell their stories to increase the empathy; the defenders of victims may write how they stopped the bullying to encourage the other students; or the bystanders can explain how passively observing the bullying may increase the problem.

Fourth, especially the negative link between self-reported perceived unpopularity and bullying indicated that the bullies/perpetrators are not the ones who must be fought against but the ones who must be helped. The students who bully others seem to be aware about their negative impression and unfortunately this awareness makes them bully more. Therefore to break this reciprocal link, the emotional motives behind the bullying must be included in any kind of intervention.

Fifth, the negative link between cyber-prosocial behaviors and face to face bullying clearly indicated that any intervention or prevention program must equally take school bullying and cyberbullying into account. The students in the world (except some countries which restrain internet penetration or countries with worse internet infrastructure) has born and grew with Information Communication Technologies (See Zych, Ortega-Ruiz and Del Rey's (2015) review which focus on disadvantaged populations related with face-to-face bullying and cyberbullying). Therefore they are called digital nomads as explained above. Neglecting this reality will only postpone the solution of problems related with bullying and victimization. As Tokunaga (2010) defined in his review article: it follows you home from school. A recent research by Chan and Wong (2015) also showed how school bullying and cyberbullying can be included in a whole-school intervention approach.

4.2. Conclusion

As a conclusion despite some limitations such as relatively small sample, self-reported measures, a short term longitudinal data, and the quantitative nature of the research (see Thornberg (2011) for a review on qualitative research related with school bullying) the current findings have the potential to be integrated to both national and international prevention/intervention programs as risk/protective factors. Also the empirical findings may have future directions for following research. So, it can be said that the current research had both theoretical and practical implications.

ABOUT THE AUTHOR

Fatih Bayraktar is an associate professor in Developmental Psychology at Eastern Mediterranean University (EMU) Faculty of Arts & Sciences Department of Psychology. His research interests include prosocial-antisocial behaviors among adolescents; Internet use/misuse among adolescents; Resilience; Bullying/cyberbullying; Minority children/adolescents and their online risks/opportunities; and Parental mediation strategies. He is the chair of EMU Psychology Department and member of Turkish Psychological Association, European Society for Developmental Psychology, European Association for Research on Adolescence, and International Society for the Study of Behavioral Development.

Chapter 127

EXPERIENCES AND MEANINGS OF BULLYING AMONG BULLIES, VICTIMS, AND BYSTANDERS IN AN ALL-GIRLS SCHOOL

Merimee Tampus-Siena*

Office of Student Affairs and Student Services
Philippine Normal University, Manila, Philippines

ABSTRACT

This study used phenomenological research design to explore the bullying experiences and determine the meaning of bullying among fourteen Grade 4 to Grade 8 female students in an all-girls school as identified bullies (N = 5), victims (N = 6), and bystanders (N = 3). Findings of this study showed that a student can play more than one role in the bullying circle; that is, they can either be a bully, a victim, or a bystander, or all those three. Furthermore, bullies, victims, and bystanders understood that the bullying experiences they had were caused by the bullies' dislike of the victims and that the victims were not randomly picked. Bullies, victims, and bystanders formed different meanings of their bullying experiences based from the roles they played in the bullying circle. Results are indicative that an effective anti-bullying program must be developed based from the bullies', victims', and bystanders' understanding of the bullying phenomenon.

Keywords: bullying, bully, victim, bystander, phenomenological research

INTRODUCTION

Bullying involves a desire to hurt others manifested through hurtful actions, power imbalance, repetition of unjust use of power, and evident enjoyment by the aggressor, with a sense of being oppressed on the part of the victim (Rigby, 2002). A student is bullied when he

* Corresponding Author's Email: tampus.mu@pnu.edu.ph.

or she is exposed repeatedly and overtime to negative actions done by one or more persons (Olweus, 1993).

Bullying is damaging to the bullies, victims, and bystanders. Those who experienced bullying are more likely than others to suffer serious psychological problems later in life (www.kenrigby.net). They are more likely to experience depression and anxiety, increased feelings of sadness and loneliness, and loss of interest in activities which may persist through adulthood. Their academic achievement may also decrease (www.stopbullying.gov/at-risk/effects/). Bullies also suffer long term effects of their acts when they engage in violent and risky behaviors until adulthood. They get into frequent fights, get poor grades, perceive negative climate in school, and commit crimes (www.gomasa.org). Bystanders, on the other hand, are also negatively affected by bullying. They feel that they are in an unsafe environment. They are also fearful, feel powerless to act, experience guilt for not acting, and are tempted to participate in bullying (www.violencepreventionworks.org). Bullying destroys the fundamental concept of order in the society (Mapue, 2010).

In the Philippines, the Philippine Women's University, Council for the Welfare of Children and United Nations Children's Fund (PWU-CWC-UNICEF) Plan for the Philippines in 2009 recorded that 73.58% of children in Grades 4-6 and 78.36% in high school surveyed in urban areas have suffered verbal bullying from their peers, 30.17% of children in Grades 4-6 and 37.57% in high school surveyed in rural areas experienced physical bullying. In 2008, a study released by a child rights monitor in the Philippines showed that "at least five out of 10 children in Grades 1-3, seven out of 10 in Grades 4-6 and six out of 10 in high school have experienced some kind of violence in school" (France-Presse, 2008). Ridicule, teasing, being shouted at or cursed are common forms of bullying, with physical violence most common among male children, the British-based study added.

Television and newspaper reports reveal the continuing prevalence of bullying in the Philippines. These reports showed how bullying resulted to death and threats of physical harm which happened in different public and private schools in the country. For example, on September 28, 2012, two students who wanted to avenge their bullied classmate punched, kicked slapped without provocation and pointed a gun to a 17-year-old student in a public school in NCR. Another was last February 3, 2013 when a 14-year-old high school male victim from Quezon City, died after his 13-year-old classmate bullied him. Cyberbullying was blamed for death of a 14-year-old male student of a private Catholic school in Batangas who shot himself on March 18, 2013. On August 9, 2013, a grade school boy from Naga died after his classmates bullied him by punching him and twisting his arms. Meanwhile last October 5, 2013, *Bandila* ABS-CBN News Channel, reported another bullying case where new young volleyball athletes from a notable Catholic University received harsh initiation rites from the senior athletes.

Republic Act 10627 or the "Anti-Bullying Act of 2013," approved last June 6, 2013, prohibits bullying in the elementary and secondary school throughout the country. The bill defines bullying behaviors in schools and authorizes schools to impose sanctions on student bullies. All elementary and high schools are required to provide anti-bullying policies and programs and to sanction students who are found guilty of bullying their classmates.

With the above-statements, it can be implied that bullying is a sounding problem not just in other countries but also in the Philippines today. This, what Filipinos have considered before as "*away-bata*" (children's petty quarrels) turned out to be a serious dilemma in the Philippine

schools. Responding to these bullying situation calls for a deeper understanding of the dynamics of the said phenomenon.

Bullying has been studied for so many years in other countries and in the Philippines. However, there is a scarcity of research on school bullying in the Philippines (Bayhon, 2001) and in cases when research on this is undertaken, it is still yet in its infancy (Zorilla, 2012). Also, there are a limited number of qualitative studies on bullying especially in the Philippine context.

The Anti-Bullying Act of 2013 has not yet reached the stage when it becomes a full blown law after its approval. Schools are still in the process of complying with the requirements set by the law. It is only when a clear definition and description of bullying experiences in school can the educational system address them by designing appropriate intervention programs that can adequately deal with bullying (Oano, et al., 2013). More importantly, it is only when the lived bullying experiences of bullies, victims and bystanders can schools take in hand with efficient counseling methods and proper intervention for those who have been part of the bullying experiences.

Conceptual Framework

Using Phenomenological Research Design, this study explored the bullying experiences of children and the meaning they developed from their bullying experiences.

Bullying is defined as negative actions done to a victim repeatedly and over time by one or more persons with evident enjoyment on the part of the bully and a sense of being oppressed to the victims. It involves power imbalance and the bully's desire to hurt (Rigby, 2002; Olweus, 1993). According to Olweus in the website *The Knowledge Network for Innovations in Learning and Teaching* (2010), in order for bullying to occur, three individuals or group of people must be involved: the bullies, victims, and bystanders. Bullies repeatedly use power to physically and/or psychologically harm their victims; victims who are targeted by the bullies and are exposed repeatedly and overtime to negative acts done by the bullies; and the bystanders, who are anybody, aside from the bullies and victims, present during a bullying incident. The bystanders may have ignored the event entirely, may have witnessed bullying but did not do appropriate actions to stop it, may have witnessed the event and did direct intervention to stop it or helped the victim, or may have engaged in the event by supporting the bully (Coloroso, 2002).

Sutton (2001) used the theory of mind (TOM) framework in exploring bullying. Theory of mind is a branch of cognitive science which investigates how persons ascribe mental states to other persons and how they use the states to explain and predict the actions of those other persons. It investigates mind reading or mentalizing or mentalistic abilities (Marraffa, 2014). Sutton (2001) believed that strong TOM skills is useful in certain kinds of bullying: spreading gossip, social exclusion, organizing gangs and avoiding detention—forms of bullying common among girls (Murphy, et.al., 2009). In his study, Sutton (2001) distinguished 'bullies' from their 'assistants' and 'reinforcers,' 'defenders' and 'victims.' Similarly, this study identified the participants' roles in the bullying experiences they had as a bully, a victim, or a bystander ('assistants', 'reinforcers' and 'defenders' classified as bystanders).

Oliver and Candappa (2003) emphasized the significance of starting with the children's bullying experiences and taking into account their perceptions of the effectiveness of the school

in handling such experiences. This study started from exploring the bullying experiences of children. Anchored in phenomenology, Faber (1996) said that it is necessary to begin with the conscious experience of an individual to achieve certainty. Husserl elaborates that natural knowledge begins with experience and remains within the experience (Natanson, 1973).

From these experiences, children develop their descriptions and their perspectives of the experiences (Patton, 1990). From these perspectives, they understand and make meaning of their experiences (Smith, 2013). The theory of mind also served as a basis of describing how the students ascribed mental states in the understanding and meaning of their bullying experiences.

Purpose of the Study

Using Phenomenological Research Design, this study looked into the lived bullying experiences of a bully, a victim, or a bystander and how the students understand and give meaning to this phenomenon. Although a range of issues was covered during the interviews, this article gives a picture of how bullying occurs in an all-girls school; the children's understanding of bullies, victims, and bystanders, their behaviors, and their emotional experiences.

METHODOLOGY

Research Design

This study used Phenomenological Research Design (Groenewald, 2004) in drawing out, describing, exploring, and analyzing bullying experiences of children. It was selected for the intention of discovering the experiences of the students as it was lived by them. Also, this method is deemed to be useful in assessing the student's perception to the interventions done by the school to resolve their bullying experiences and the meaning they developed from them.

Phenomenological approach focuses on the descriptions of what people experiences and how it is that they experience what they experienced. A researcher can use a general phenomenological perspective to explain the importance of using methods that capture people's experiences of the world without conducting a phenomenological study that focuses on the core of shared experience (Patton, 1990). Phenomenological researchers examine the perceptions or appearances from the point of view of the participants from what things really are (Campbell, 2011). A phenomenologist must have an understanding of the existence of others' experiences through one's own consciousness (Quito, 2001). They are fully interested in the important relations and structures and not facts or events. Moreover, to achieve certainty in knowledge, it is necessary to begin with the conscious experiences of the individual (Farber, 1966). Husserl elaborates that natural knowledge begins with experience and remains within the experience (Natanson, 1973). In the conduct of phenomenological method, a researcher must be in direct contact with the phenomenon itself, assume that he/she does not know the phenomenon but wishes to, and use methods which will portray human experience in experiential terms (Seamon, 2000).

Sampling Procedure

The Student Formation Coordinator and the Guidance Facilitators were asked, in their discretion, for the names of all the students who were reported to be part of bullying, either as bully, victim or bystander for school year 2013-2014.

Criterion sampling was utilized to select specific participants in the study and limit them in number. The cumulative records and anecdotal reports of the participants were reviewed by the researcher and middle school girls had to meet at least two of the following criteria for inclusion in the study: (1) Involvement in bullying either as a bully, victim or bystander over a period of time (bullying which lasted for at least one week); (2) Has been part of bullying either as bully, victim, or bystander repeatedly (at least three or more times); (3) Involvement in bullying where the victim reported significant physical and/or emotional pain or trauma; (4) Bullying experience where perception that the bully is stronger than the victim is evident; and (5) Part of a bullying case where the bully was sanctioned by the Student Formation Coordinator and/or was counseled by the Guidance Facilitator.

Participants of the Study

The participants of this study are five identified bullies (Grade 4 = 1, Grade 5 = 1, Grade 6 = 1, Grade 7 = 1, Grade 8 = 1), six identified victims (Grade 4 = 1, Grade 5 = 2, Grade 6 = 1, Grade 7 = 1, Grade 8 = 1), and three identified bystanders (Grade 4 = 1, Grade 6 = 1, Grade 8 = 1).

Each participant was given a pseudonym which came from the names of the researcher's friends and from the list of the popular names in the website www.babynames.familyeducation.com/popular-names/girls/ and has no connection whatsoever with the real names of the participants.

Identified Bullies

Jessica: a 10-year old grade 4 pupil who cyberbullied her classmate on August 2013.

Erika: a 10-year old grade 5 pupil who teased, physically harmed, and verbally harassed her classmates from June to July 2013. She was placed under strict disciplinary probation.

Marianne: a 12-year old grade 6 pupil who socially excluded her classmate in October 2013. She also got involved in verbally harassing another classmate.

Rosette: a 12-year old grade 7 student who was reported for teasing and socially excluding a classmate on September 2013.

Sheriline: a 13-year old grade 8 student who cyberbullied, name-called and teased a classmate on July 2013.

Identified Victims

Gwen: a 9-year old grade 4 pupil who was cyberbullied by her classmates without her knowledge.

Tyra: a 10-year old grade 5 pupil who was verbally bullied by her classmate on June 2013. Her grandmother was the one who reported to her previous class adviser about the bullying. Her oppressor was reprimanded by her class adviser.

Mary Joy: a 10- year old grade 5 pupil who was physically bullied by her classmate on July 2013 and was verbally harassed on December 2013.

Aimee: an 11- year old grade 6 pupil who was insulted and verbally harassed by her classmate. The verbal bullying lasted for more than three months.

Olivia: a 12- year old grade 7 pupil who was teased and socially excluded by her friends on September 2013. She underwent counseling and was referred for a professional help from an external professional, particularly from a psychologist, as requested by her mother.

Ava: a 14- year old pupil who was cyberbullied, name-called, and teased by a classmate.

Identified Bystanders

Emily: an 11- year old grade 4 pupil who reported the cyberbullying perpetrated by her classmates. Primarily, she got herself involved in cyberbullying but eventually reported the case to the guidance facilitator. She claimed she was haunted by her conscience and saddened by her action.

Mia: an 11- year old grade 6 pupil who comforted a classmate deliberately excluded by her friends from the group. In the interview, she shared a lot of stories about bullying which she witnessed this school year. Her friend refused to go back to school because of what had happened.

Madison: a 13- year old grade 8 student who witnessed how her friend was cyberbullied on Twitter, Facebook, and Instagram. She also heard gossips about her. Her friend left school after what had happened.

Research Instruments

The main research instrument used in this study is semi-structured interview consisted of questions in response to the purpose of this study. In the conduct of the semi-structured interview, the researcher made use of an interview guide which roughly contained the topics to be covered as well as the sequence of the questions. Three interview guides were prepared: Interview Guide for the Bullies; for the Victims; and for the Identified Bystanders. Although the items in these three interview guides were the same for the three groups, these were rephrased according to their roles in the bullying situation.

Journal writing was another tool used to gather data. If participants felt at ease more on writing than speaking during the interview, they were asked to write essays or journals which could fully discuss their thoughts and feelings about their experiences.

Data Gathering Procedure

This study made use of semi-structured, open-ended questions during the data collection phase of this study. The interview was conversational. The participants were encouraged to answer the questions as if they were telling a story. They were free to speak either in Filipino and in English but the questions were asked in English.

The researcher allowed the participants to have some control in the interview but did not lose track of her purpose and tried to redirect them especially when they were telling stories not related to their bullying experiences anymore.

Debriefing followed after the interview. This was to process some tension or anxiety after the participant opened up personal and emotional experiences and wondered about the interview's purpose and how the information would be used (Kvale, 1996).

Explication of Data

The data gathered from the 14 transcribed interviews (with the accompanying researcher's field notes) and one journal (written by one participant) were analyzed and underwent explication, or the investigation of the constituents of the phenomenon while keeping the context of the whole (Groenewald, 2004). The researcher searched through each participant's statements for those that were especially relevant—those that appeared to be particularly meaningful to the participants. Units of meanings were formed into themes which were then summarized to validate each theme. The synthesis of the findings of the study was presented in a manner analogous to assembling a jigsaw puzzle.

This study followed Hycner's explication process as demonstrated by Groenewald (2004). Explication of data was used in this study because according to Hycner (1985), the term analysis means breaking into parts whereas explication implies investigation of the elements of the phenomenon, while keeping the context of the whole. Since phenomenology is concerned with the essence of an experience from the perspective of the participant, the researcher must keep the whole intact and must not be dismissed because of the process (Valentine, Analysis or Explication, 2011).

This explication process has five steps, namely:

1. Bracketing and phenomenological reduction
2. Delineating units of meaning
3. Clustering of units of meanings to form themes
4. Summarizing each interview, validating it, and where necessary, modifying it
5. Extracting general and unique themes from all the interviews and making a composite summary

(Groenewald, 2004)

Validity and Credibility

After the generation of core ideas, subthemes and major themes, the researcher submitted the raw data (transcriptions) to an expert for cross-analysis. The researcher discussed with her the context of the study, findings, insights, and perceptions. The cross-validator then checked whether the raw data matched with the core ideas classified by the researcher. She also changed the words used by the researcher for the core ideas to better represent the meaning derived from them. Appropriateness and clarity of the subthemes and major themes in representing each core idea were also checked.

After the core ideas, subthemes and major themes were cross-analyzed done by an external auditor who validated the findings of the study. External auditing means having another person not involved in the research process examine both the process and the product of the research

study. Its purpose is to evaluate the accuracy and evaluate whether or not the findings, interpretations, and conclusions are supported by the data (www.qualres.org). The external validator is also an expert in qualitative research and a developmental psychologist.

Another procedure used in validating the data gathered was member checking where the participants themselves re-read and checked whether the researcher translated the interviews in accurate words.

RESULTS AND DISCUSSION

The Bullying Experiences

Bullies', victims' and bystanders' identified in this study experienced verbal, physical and indirect bullying. Most participants (N = 12; 85.7%) experienced verbal bullying such as name calling, teasing, derogatory remarks, being shouted at and threatening. They also experienced indirect bullying (N = 11; 78.6%) such as social isolation, rumor-spreading, and cyberbullying. Some experienced physical bullying (N = 6; 42.9%) in the form of hiding things, tripping and hitting.

In relation to age, common among this middle-school participants were verbal bullying (12 out of 14 participants) in the form of name-calling, teasing, receiving derogatory remarks, being shouted at and being threatened; and indirect bullying (11 out of 14 participants) in the form of social isolation, rumor-spreading and cyberbullying. This confirms the National Survey of Children's Exposure to Violence in 2013 which revealed the drop off of physical bullying compared to emotional bullying as age increases (Child Trends Data Bank, 2013).

In bullying, participants of this study commonly experienced not a single role of being a bully, a victim or a bystander—victim turned into a bully, bystander turned into a bully, bully turned into a victim, bystander turned into a victim, victim turned into a bystander, and bully turned into a victim then into a bystander.

According to the website *The Knowledge Network for Innovations in Learning and Teaching* (KNILT) in 2010, the bullying circle was developed by Olweus and in order for it to take place, three individuals or three people must get involved: the bullies, the victims, and the bystanders. The website added that the bullying circle is how the role players in the bullying situation react and participate in the bullying.

Figure 1 shows that the participants in this study (N = 12; 85.7%) played more than one role in the bullying. Three identified bullies turned into victims; one identified bully became a bystander; one victim turned into a bully; one identified victim was a bully; two victims were bystanders; two bystanders were victimized; and two participants from being a bully, became a victim and then a bystander.

Social influence can also be perceived as the cause of the bystanders' transformation from being a bystander to a bully and being a victim to a bully. The participants' claims that bullies learned their behavior from what they have seen from others which they thought to be correct as well as the behavior they learned from their own oppressors may have caused them to resort into bullying.

Figure 1. Changing of Roles in the Bullying Circle.

It is important to note that none among the participants turned into a bystander from being a bully but there were those bullies who turned into a bystander after being victimized. From this, we may suggest that the bully, herself, has to experience victimization before choosing to be just a bystander.

Meanwhile, common action done by victims and bystanders was standing up against bullying; however, there were still those victims and bystanders who chose not to act for fear of the bullies' retaliation or because acting will just make the situation worse. Most bystanders choose not to act for fear that they will be the next target of the bullies (www.eyesonbullying.com). In this study, victims chose to ignore the incident and keep quiet. Four participants who experienced victimization said that they just kept quiet and let the bullies bully them. In their narratives, they use words such as *binale-wala* (disregarded), *pinabayaan lang* (let out), *hindi pinansin* (ignored) and *tahimik lang* (kept quiet).

"Ginawa ko na po yun siguro ilang beses, kaso binabale wala lang po nila yun...Hindi na lang po ako nagsasalita..." ("I did that a lot of time but they just disregarded it so I just kept quiet") Marianne as Victim, Grade 6, 12 years old

"Teacher hindi ko na lang siya pinapansin, yung mga sinasabi niya. Kasi teacher tahimik na lang ako." ("Teacher I ignored them, everything she said. I just kept quiet") Mary Joy as Victim, Grade 5, 10 years old

"Ah.. Wala... ako teacher hindi ko na pinapansin. Kasi wala rin naman magagawa pag papansinin ko eh. Papalakingin ko pa...." ("I just ignored them. Nothing will happen if I will pay attention to them. The problem might become bigger if I do") Aimee as Victim, Grade 6, 11 years old

On the other hand, some bystanders comforted the victims. One remarkable response was from Mia when she told the victim to pray for the bullies.

"I told her not to make them pansin na lang. Just... just pray for them or whatever. Coz, coz if... you should be yourself naman pero if there's something bad about you, you should change it but no one's perfect naman siguro di ba." ("I told her to ignore them and just pray for them. I told her to be herself. If there is something bad about you, you should change it but no one's perfect anyway") Mia as Bystander, Grade 6, 11 years old

Another meaningful word came from Olivia when she told her classmates who got victimized that the bullies won't be successful in the future because of their wrongdoings.

“Pero pag sumosobra na, nakita ko nang umiiyak, sinasabihan ko na po yung ano, yung nabully na, yaan mo na lang sila, kasi someday, ikaw din naman magiging successful kesa mas sa kanya eh... Kasi siya yung nabully.” (“But when it is too much, like when I saw someone crying, I tell the victim to ignore them because someday, she will be more successful and better than the bully”) Olivia as Bystander, Grade 7, 12 years old

One unique response came from Aimee when she apologized to the bully because she thought that it was her fault and not the bully's. She believed that it was her fault that's why she got bullied.

Among bullies, it was their mothers who first knew of the bullying experiences. Participants also tell their bullying experiences to their guidance facilitator and friends. One told her sister and father and another kept the experience to herself.

Meaning of the Lived Bullying Experiences

The Ones Who Bullied

In this study, eight out of 14 participants (57.1%; Gr4 = 1, Gr5 = 2; Gr6 = 2; Gr7 = 1; Gr8 = 2) admitted that they bullied their classmates this school year. The participants said that they bullied their classmates because they dislike them. They found them to be annoying, *maarte*, immature, naughty, easily-angered, boastful, too sensitive and mean to others. They also bully their classmates to release their anger towards them. Bullies rationalize their actions. For them, they did not really mean to hurt them, that they're attitude was really like that or that the victim deserved to be bullied. Some also said that they learned bullying from their past experience of victimization or they were influenced by other people to do it.

Similar to Ong Ante's study in 2001 and Williams' in 2008, the participants in this study who experienced bullying others felt regret after realizing their mistakes (N = 5; 62.5%). They regretted their actions and wished to correct them. In William's study in 2008, bullies regretted their actions when the victims confronted them, when there were members of their families who experienced victimization and those who were affected of the bullying they did. Likewise, the participants in this study regretted their actions upon realizing that their actions gave negative Effects to the ones they bullied. Also, they regretted that they received sanction from the school.

The participants who bullied their classmates also experienced repression. They said that they forgot some details of their experiences, especially the reasons why they hurt their classmate. In addition, bullies also experiences fear that the teachers will find out about their bullying behaviors and reprimand them.

What is really remarkable in this study is that the bullies felt empathic towards their victims. They were aware of what their victims feel towards them and with regards to their victimization. Some said that they know that their behaviors were hurtful to others, noticed that their victims felt sad when they left them out, felt pity towards them and perceived that their victims were annoyed of their bullying behaviors (N = 4; 50%).

Empathy is defined as experiencing the emotional state of someone else (Lamia, 2010). Common sense may tell that bullies lack empathy. Andreou (2013), in his study of primary students in Greece found out that compared with pupils who were not involved in bullying, bullies were more likely to endorse Machiavellian beliefs—moral disengagement which permit people to harm others without suffering the pangs of conscience (Dewar, 2013). Meanwhile, Zorilla (2012) emphasized empathy in her study of high school students and developed an empathy-building program. Her study revealed that a good number of bullied showed empathic concern. Similarly, Lamia (2010) said that bullies have the capacity to empathize. However, they use empathy to manipulate and to cause pain to others. They withhold their compassion in order to give distress to others. This supports Sutton's (2001) idea that bullies have a strong mind that is why they can manipulate friendships.

Another significant result in this study is when one participant admitted that she enjoyed bullying her classmates as a result of her past experience of victimization. It can be implied that she was satisfied of her actions because she felt superior when she bullied others after her inferiority feelings when she got victimized.

In their bullying experiences, the participants perceived their victims feelings of guilt when the bullied was sanctioned because of them and feelings of fear that the bully will retaliate when they report them. Meanwhile, they saw bystanders as persons who do not really care about the victims but interested for rumors about bullying.

The Ones Who Are Bullied

In this study, 13 out of 14 participants (92.9%; Gr4 = 3, Gr5 = 4; Gr6 = 3; Gr7 = 2; Gr8 = 2) admitted that they experienced bullying victimization. Most of them said that they got bullied because the bullies dislike them ($n = N$; 38.5%). The bullies found them *maarte* and were annoyed of them. Some participants experienced victimization because they got backed at by the bullies ($N = 3$; 23.1%). They said that they had past mistakes to the bullies which the bullies did not forget. One participant said that she got bullied because her classmates wanted to test if she will fight back. Another said that the reason why she got bullied was because her classmate felt threatened that she might replace her in being the leader of their batch.

Victims felt socially isolated ($N = 5$; 38.5%). They felt as if they had no friends, they were abandoned and that nobody loved them. The victims also felt sad ($N = 4$; 30.8%) because of the pain inflicted to them and because the experience deepened their sadness in school. Two of the participants (15.4%) who got bullied felt so frustrated to fight back to the bully. One victim said that she felt scared to fight back because the bullies might retaliate and bully her more. Similar to this result was that of Rana in 2006. In her phenomenological study of victims, she concluded that victims felt fear and dread. Learned helplessness was also a common feeling for some of the victims ($N = 3$; 23.1%). Victimization was a common school experience to them because it happened almost every day. Victims with this kind of mentality were called perpetual victims. Perpetual victims are students who are victimized all their life. These victims might have developed a victim mentality where being victimized becomes part of their being (Definitions/ Characteristics of Bullying, 2009). Other emotional experiences the victims had were inability to defend self, anxiety, hopelessness and unwillingness to retaliate.

For victims, bullies are mean because they want to see victims' misery and that they encourage others to join them in bullying. Also, victims said that bullies are popular and see themselves as popular. Victims said that bullies have small chance to change themselves, They do not believe that bullies will be changed even by intervention programs because they still

bully after being subjected to it. Victims perceived bullies as someone who has stronger personality compared to others, are seniors or someone older than the victims, want to seek attention, immature, and have learned their behavior and got used to it. They also said that bullies fail to recognize their own behavior. They bully others for the same reason that they also do and do not realize that their actions are wrong. Similar to the phenomenological study of Nash in 2011, the participants of this study also viewed bullies as insecure individuals and that they wanted to validate their power by targeting innocent and inferior victims.

Talking about bystanders, most victims have negative perception of them (N = 4; 30.8%). Victims believe that bystanders are influenced by the bullies to join them in bullying. For them, the bystanders do not want to help them and do not feel that they were in pain. Bystanders were also perceived as feelingless and untrustworthy. Bystanders also do not stand up against bullies or defend the victims because they were scared to be the next target of the bullies. Similarly, Lamia (2010) said that bystanders' fear of being excluded or being bullied themselves allows their collusion with the bullies.

The Ones Who Witnessed Bullying

In this study, six (N = 6; 42.9%) of the participants shared their experiences as bystanders. For bystanders, they were just influenced by the bullied into joining them in bullying.

In their experience as a bystander, all of the (N = 6; 100%) felt empathy towards the victims. They felt pity and sad for them and felt that whoever was in their position would be in too much pain. They also felt sad for the bullies because they bully just to let out their feelings, regret of defending the victims because of the negative consequences they received from the bullies and guilty of being involved in the bullying. Gordon (2010) believed that bystanders, in a bullying situation experience fear and are weighed down with guilt. This combination of fear and guilt caused them to have the strong desire to help but an equally strong desire to avoid the situation. The anxious feeling of being targeted, may also be the bystanders' reason of joining in bullying as a coping mechanism (Gordon, 2010).

Bystanders, in their bullying experience, believed that victims did not want to be helped, they are in pain and they hate themselves. Meanwhile, for them, the bullies felt angry of their victims, insensitive of the victims' feelings because they do not care about how they feel and consider their behavior as an unserious act and felt ashamed of their behavior. Most bystanders (N = 3; 50%) said that bullies bully because of dislike. Also, they bully to get attention from other, especially from the teachers. Bullies also have family problems, want to be popular, receive social support so their bullying behaviors are strengthened and are threatened of the victims' abilities in the sense that victims will perform better than them in the class. Other bystanders, for the participants, join in bullying because they were influenced by the bullies but felt sad when they got included in bullying. On one hand, there were bystanders who ignore the bullying event or joined in because they were interested of rumors.

CONCLUSION

In the light of the findings, the following conclusions were drawn and are limited to the number of participants in this study and their experiences:

1. Bullying experiences of girls mostly include verbal bullying such as teasing, receiving derogatory remarks, being shouted at and being threatened and indirect bullying such as isolating from the group, rumor-spreading and cyberbullying.
2. A student can play more than one role in a bullying circle. They may have experienced hurting or bullying another classmate, being bullied or witnessing another person being bullied or all the three roles—bully, victim and bystander.
3. Bullies, victims and bystanders understand that the bullying experiences they had were caused by the bullies' dislike of their victims and that the victims were not randomly picked.
4. Bullies regretted their actions and experienced empathy towards their victims but used this feeling to manipulate and hurt others. Some bullies also tend to repress what they did for the trauma which the experience brought them.
5. Some victims believed that bullies have a small chance to change and that intervention programs wouldn't bring immediate change to the bullies' behaviors. They also believed that bullies enjoy when they hurt others but not all bullies admitted such feeling of happiness.
6. Some victims see bystander's unwillingness to help them in a bullying situation while some bystanders see the victims' refusal to be helped by them.

RECOMMENDATIONS

Guidance counselors must understand clearly the dynamics of the bullying phenomenon and how it is experienced by bullies, victims and bystanders before giving them counseling and in providing effective anti-bullying program. Educators who wish to provide bullying intervention program must create one which would respond to the needs of all its role players—bullies, victims and bystanders. Teachers must handle bullying reports appropriately. They must assure the students of its confidentiality.

ABOUT THE AUTHOR

Merimee Tampus- Siena is a graduate of Bachelor of Arts in Psychology at the National Teachers College in 2010 (top 1 among psychology graduates and top 2 among batch 2010 graduates) and Master of Arts in Education with specialization in Guidance and Counselling at the Philippine Normal University, the National Center for Teacher Education in 2014. Currently, she is taking up Doctor of Philosophy in Clinical Psychology at the Ateneo De Manila University. She is a licensed Professional Teacher and a Registered Guidance Counsellor, Top 9 in the board examinations for guidance counsellors in August 2014. She worked as a preschool and grade school guidance counsellor at Colegio de Sta. Rosa– Makati for five years. Currently, she is working as a faculty/ counsellor at the Philippine Normal University where she is also the Coordinator for Student Activities of the Office of Student Affairs and Student Services. She teaches psychology and professional education subjects to university students. Her research interests include qualitative research, counselling and psychotherapy, bullying, student development and mindfulness. She is a caring mother to Ariadne and a loving wife to Jhun.

Chapter 128

PARENTS' PERCEPTIONS ABOUT BULLYING

Eleni N. Nikolaou and Panagiotis J. Stamatis*

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

Bullying is a pervasive problem which has a profound impact on the development and psychosocial adjustment of children. It is well documented that preschool children exhibit all forms of bullying (physical, verbal, relational). Moreover, parents have a vital role in preventing and intervening in bullying situations. Parents' involvement in school-based prevention is of fundamental importance. Their views influence their responses. The aim of this study was to explore parents' views about bullying at preschool age. A questionnaire was developed based on previous research. The findings indicate that the parents of this sample value the collaboration between school and family, the implementation of socio-emotional interventions in school context as well as the activities for diversity tolerance within the classroom. Moreover, they regard that interventions for preschool children should include emotion recognition and expression skills, emotion regulation, anger management and impulsiveness control skills. The results of this study could be utilized in designing school-based prevention programs at early childhood settings, as a key component of the effectiveness of anti-bullying programs is their implementation at preschool age.

Keywords: bullying, children, communication, early childhood, family relationships, interpersonal relationships, parents, preschool age, preschoolers, perceptions

INTRODUCTION

Bullying is a widespread social phenomenon which has gained international attention. It emerges in early childhood settings (e.g., Alsaker & Gutzwiller-Helfenfinger, 2010; Nikolaou

* Corresponding Author's Email: stamatis@rhodes.aegean.gr.

& Markogiannakis, 2018) and it is a risk factor for children's development, as it is associated with psychosocial adjustment difficulties (Nansel et al., 2001). Bullying is conceptualized as a form of aggression which is repeated over time. There is an imbalance of power between the victim and the perpetrator, who have the intention of harming victims (Olweus, 1993). All forms of bullying (physical, verbal, relational) are observed in preschool classrooms and playgrounds (Crick, Casas & Ku, 1999). Relational aggression which aims to damage children's relationships is common among young children (Crick et al., 2004). It includes spreading nasty rumors and social exclusion. Within this framework, the purpose of the present research was to explore parents' perceptions about bullying. Goryl, Neilsen-Hewett & Sweller (2013) point out the importance of anti-bullying policies in early childhood settings. Parents' perspectives who are among the stakeholders for implementing anti-bullying policies are crucial to bullying prevention.

There is limited research conducted regarding parents' perceptions about bullying. The social-cognitive model posits that perceptions motivate behavior (Bandura, 2001). Parents' views on harassment from peers impact their responses to peer victimization and are associated with children's well-being. Parents' beliefs are also linked to their socio-emotional development and their misconceptions about bullying may have negative effects on children's adjustment, as they can lead to inadequate emotional support and parental assistance (Troop-Gordon & Gerardy, 2012). Children's reactions to peer victimization may reflect their parents' beliefs about coping strategies.

Parents' conceptualizations about bullying affect their responses and moreover they have an impact on children's disclosure of their victimization. Children are often reluctant to bring a bullying incident to the attention of their parents and school personnel. Therefore parents should be alert to the unusual behaviours that children who are victimized display, signs and indicators of bullying. Parents' definitions of bullying are consistent with the relevant literature (Sawyer et al., 2011).

Bullying prevention is essential to be based on a social-ecological perspective. Bullying is a social phenomenon that is determined by multiple factors associated with the contexts in which children are embedded (family, peer group, school, community and culture). The characteristics of these contexts interact and produce bullying behaviour. Therefore, family and school systems collaboratively shape the identity of bullies and victims (Espelage & Swearer, 2011). Parental use of corporal punishment, poor parent-child communication, lack of parental monitoring, high family conflict, maternal and paternal depression, poor relationships with classmates are among the risk factors associated with bullying (Shetgiri, 2013). Authoritarian child-rearing practices, parental punitiveness and aggression are family variables that make children vulnerable to aggression (Ahmed & Braithwaite, 2004). School variables that are considered risk factors are teacher attitudes, and school climate. Societal factors include discrimination, racism and prejudices (Swearer-Napolitano, 2011). In addition, preschool behavioral, emotional and motor problems, socio-economic status and family breakup have been linked to bullying at a later age (Jansen et al., 2011).

Parent intervention is considered a crucial factor in bullying prevention. The collaboration of parents with school administrators, teachers and staff contributes to the effectiveness of bullying (Demaray et al., 2013; Stamatis & Nikolaou, 2016; Nikolaou & Markogiannakis, 2017). Parent involvement in bullying prevention is a critical aspect of addressing bullying. Parents should be involved in anti-bullying initiatives and participate in developing strategies for countering this phenomenon.

PREVIOUS RESEARCH ABOUT PARENTS' PERCEPTIONS REGARDING BULLYING

Smorti, Menesini, & Smith (2003) investigated parents' definitions about bullying, as it influences the communication with their children about bullying episodes. The participants in their research took into account characteristics such as the imbalance of power between the bully and the victim, and repetition of the aggressive actions. They recognized various forms of bullying incidents and distinguished fighting from bullying. They also identified verbal, physical and social types of bullying.

Mishna, Pepler & Wiener (2006) found that the participants included direct and indirect forms in their definitions. They were aware of the power imbalance and the intent to cause harm which are integral to bullying, although they did not mention repetition. However, the majority of the respondents tended to underestimate the impact of indirect forms of bullying. In some instances they found it difficult to distinguish bullying from teasing. Half of the parents were not aware of their children's victimization.

In Repo's study (2015) parents perceived bullying as a part of normal development. Participants also found it difficult to distinguish bullying from quarrelling and believed that preschool children are not yet capable of controlling their aggressive behaviour.

Exclusion from play, threats and the victim's perception of being bullied were identified by parents and preschool workers as delineated by Cameron and Kovac (2016). The majority of the respondents believed that bullying can take place only once and one in four reported that there must be an intent for harming behind the behaviours regarded as bullying.

PARENTS' ROLE IN BULLING PREVENTION

Research data indicate that parents recognized the importance for collaboration between them and school personnel. They also sought the collaboration with community agents (counselling services, child psychologists, community health services). Parents reported that schools should support and provide guidance for children and parents. They expressed the need for being actively involved in anti-bullying initiatives. This research study findings advocate for improved communication between school and family. Schools are required to have clear processes, roles and responsibilities about tackling bullying issues (Harcourt, Green, & Bowden, 2015).

According to Waasdorp, Bradshaw and Duong (2011) parents responded to their children's reports of victimization by talking to their children and contacting a teacher or an administrator. These were the most prevalent strategies adopted by the majority of the participants. Gravesteijn, Diekstra and Petterson (2013) argued that parents construed bullying as a shared responsibility of school and family. Moreover, the respondents asserted that bullying rates decreased when parents and children were offered assistance by the school.

Karga (2013) found that the majority of parents in a study in Greece, regard active strategies as the most appropriate for handling bullying incidents, which involve concern and dialogue with children and prevention programs with the aim of promoting mental health, development of social skills, and cooperation with family. They expected from schools to take systematic measures for dealing with bullying. The vast majority acknowledged the importance of school-family collaboration and simultaneously they recognized their responsibility in

reducing bullying. Ratkidou et al. (2016) research findings point out the necessity for cooperation with teachers for discussing students' behaviour and several school issues. Parents in their study also expressed their need for guidance from experts regarding the phenomenon of bullying. They argued that workshops, seminars, actions and consultation from specialized staff are very critical for addressing bullying and emphasized the collaboration between all stakeholders that are involved in addressing bullying. Giovazolias et al. (2010) suggested that it is essential that all stakeholders understand the dynamics of bullying. They delineated the importance of cultivating a school climate based on respect, and an active interest for children's issues.

Engagement of families and the partnership of school personnel and family is considered a key element in violence prevention. Their knowledge, information, and experience can be utilized for designing prevention programs for students. Their perspectives are valuable. Parent education could empower a resilient family environment, as interventions are including effective strategies for setting clear limits and supporting children (Brubaker, Brubaker, & Link, 2001). Furlong et al. (2005) argued that effective approaches for establishing school safety include skills building, parent and community involvement and improved school climate. These factors can enhance the effectiveness of bullying prevention and the creation of a safe environment that will foster children's healthy development and learning (Stamatis & Ntouka, 2018).

Students' and family's participation in policy development and the implementation of programs is one of the guiding principles to bullying prevention that enhances school safety. Parents may be the members of a school safety team that establishes and communicates the roles of each member with the aim of creating a safe and supportive school environment (Rossen & Cowan, 2012).

Smith & Low (2013) posit that a key component of the whole-school approaches is the socio-emotional curricula which aim to teach children social and emotional skills. These programs can enhance positive behavior, reduce conduct problems and emotional distress. They also foster student's sense of belonging to school community and commitment to school. These programs include empathy skills such as perspective-taking skills, which is the cognitive element of empathy. These competencies cultivate the acceptance and tolerance for children who deviate from social norms and have an impact on bystanders' behavior and their attitudes toward peers. Emotion regulation skills are also part of these interventions which are associated with self-control and social problem-solving skills through which children can accurately assess social situations and cues in order to handle effectively peer conflicts. All the above competencies can eliminate social marginalization, rejection by peers and establish positive norms within the school environment. In addition, they diminish aggressive, retaliatory and emotionally reactive responses.

METHODOLOGY

Within the context of the present research, parents' perceptions of preschool children regarding the phenomenon of school bullying are explored. The aim of this research is to explore parents' definitions about bullying, as well as the prospects of bullying prevention and intervention in preschool environments.

A questionnaire was the data collection tool, which was completed by 52 participants (40 women and 12 men). The participants were parents whose children were attending kindergarten, nursery schools in three Greek regions (Crete, Rhodes and Patra). The questionnaire was based on previous research and consisted of close-ended questions and one open-ended regarding the definition of bullying. According to the analysis of data, 62% of the sample were parents with children who attended kindergarten, whereas 38% of the participants had children which attended nursery schools. The age range of the majority of participants (68%) was between 31 to 40 years old. Within the 21-30 age groups, the percentage of participating parents was 25% and within the age group 41-50, the percentage was 7%. There were no participants above 51 years old.

RESULTS

After having completed data collection, the researchers proceeded to the quantitative analysis and interpretation of data. The statistical analysis was conducted by the statistical package SPSS (v.19). The findings show that the participants regard that the following behaviors constitute bullying, as they are presented in Table 1, with the equivalent percentages.

Table 1. Parents' perceptions about the definition of school bullying

Nr	Vignette	Yes		No	
			%		%
1	"Child A is approaching child B which is one year younger, takes his toys and tells him that if he tells, he will hit him. This happens every day".	48	92.5	4	7.5
2	"Child C and his friend, almost every day wait for child D at the school's entrance, they surround him and start pushing him around and throwing his bag and jacket".	49	94	3	6
3	"Child D takes from child Z the album with his stickers to see it and tears it".	36	69	16	31
4	"Child H takes from child J the sticker album to see it and it tears it by accident. Child H is very sad about it".	16	31	36	69
5	"Child I makes fun of child K for the way he speaks, as child K does not speak Greek very well".	43	83	9	17
6	"Child L makes fun of child M for his/her new hair-cut. Child M gets sad".	41	79	11	21
7	"Child N makes fun of O for his new haircut and then both of them begin to push each other and laugh".	17	33	35	67
8	"Child P plays quietly at the yard of the kindergarten with his/her peers, when a group of children is approaching them. One of these children, child Q says: "Do not talk to P, he ingratiates himself with the teacher, do not play with him". His/her playmates leave and he/her stays alone".	46	88.5	6	11.5
9	"Child P is spreading rumors and saying bad things about Child S to the class. Most children in the class make fun of Child S and he/she stays alone most of the time".	49	94	3	6
10	"Some students do not let a classmate play with them, because he is a boy".	24	46	28	54
11	"Some students do not let a classmate play with them, because she is a girl".	22	43	30	57

The repetition and frequency of several negative behaviors were included into the goals of the present study. Within this context, the participating parents gave the following responses, which are presented in detail in Table 2. The majority of parents (67%) responded, bearing in mind that their children attend the same class as the bullies.

Table 2. Repetition and frequency of school bullying behaviors

Nr	Description of behavior	Never		1-2 times a week		2-3 times a month		Several times	
			%		%		%		%
1	I have seen or understood that a child (or some children) said bad words, made fun of or taunted another child (or some other children)	8	15.5	21	40,5	9	17	14	27
2	I have seen or understood that a child (or some children) deliberately did not play another child (or some other children), excluded him/her from his/her company or ignored him/her	11	21	26	50	6	11.5	9	17.5
3	I have seen or I have understood that a child (or some children) hit, kicked, or pushed another child (or some other children)	11	21	21	40,5	7	13,5	13	25
4	I have seen or understood that a child (or some other children) lied or spread bad rumors for another child (or some other children) and tried to make other children not like this child (or these children).	11	21	26	50	6	11.5	9	17.5
5	I have seen or I have understood that a child (or some other children) took the toy or other things from another child (or some other children) or destroyed the property of another child (or some other children).	14	27	22	42	8	15.5	8	15.5
6	I have seen or understood that a child (or some other children) threatened another child (or some other children) or forced another child (or some other children) to do things that they did not want to do	29	56	11	21	8	15.5	4	7.5
7	I have seen or I have understood that a child (or some other children) made fun of or said mean words about the country of another child (or some other children) or about the way another child (or some other children) speak Greek.	26	50	17	33	6	11	3	6
8	I have seen or I have understood that a child (or some other children) frightened another child (or some other children)	31	60	12	23	3	6	6	11

With regard to the gender of the children who exerted violence over another child, whether they displayed violent behavior against their peers or younger children, 36% of parents reported that the perpetrator was a boy and a similar percentage (34%) stated that both sexes equally exhibit violence. 24% of the parents reported that most of the time a group of boys were the bullies, whereas with regard to girls, the percentage was very low as only 4% stated that a group of girls were bullying.

Regarding the number of children that exerted violence on their classmates, the majority of parents (55%) reported that were usually seeing 2-3 persons exhibiting violence against children or against their child. In addition, a high percentage of parents (32%) stated that the violence was mainly displayed by one child. In contrast, a very low percentage of parents (5%) reported that the aggressive acts were displayed by a group of 4-9 children. Furthermore, a very low percentage of parents (8%) stated that different children or groups of children participated in every aggressive action.

Regarding the frequency of being bullied, the items that were included in the questionnaire ranged from 1-2 weeks to over a year. Based on these categories, 42% of parents answered that the victims are exposed to school bullying nearly 1-2 weeks, 21% stated that victims are exposed to violence once a month, 20% of the participants reported 6 months, 14% of the respondents one year, and 3% of the sample reported for more than a year.

Table 3. School Bullying Prevention Strategies

Nr	Prevention Strategies	1		2		3		4		5	
			%		%		%		%		%
1	School-Family collaboration	0	0	0	0	3	4	7	13	42	83
2	Collaboration between school, family and community services	4	8	5	9.5	7	13.5	10	19	26	50
3	Implementation of socio-emotional interventions (training in social and emotional skills)	1	2	1	2	5	10	11	21	34	65
4	Peer support schemes for training children to prevent and respond to bullying	1	2	4	8	11	21	9	19	26	50

Finally, regarding the place that bullying incidents are taking place, 62% of parents asserted that bullying incidents takes place in the playground during intervals, and within the classroom whether the teacher is present or not (31%). It also occurs at the corridors, staircases or at any place of the school (7%).

Table 6. Definitions of School Bullying

<i>School bullying is regarded when verbal or emotional violence is being practiced against one or all students. Violence may also come from teachers and it is difficult for parents to understand ... I do not want to mention a specific incident, but pushing a child to eat and shutting the nose, in order to bite, it can be considered violent behavior ... I believe that teachers have to go through a psychologist's committee and unexpected workplace inspection.</i>
<i>A child in a private nursery school about 4 years old, which displays autistic behaviors, with a variety of adaptation problems is subjected to bullying from peers, 2 boys who scare it or exert violence against him/her.</i>
<i>Threat "Bring me a present, in order to remain my friend".</i>
<i>To make fun of a child for his glasses or braids every day.</i>
<i>Example: To request money from a child by blackmailing.</i>
<i>A child who speaks badly of other younger or older children and offensively.</i>
<i>Not to play one of the children.</i>
<i>Anybody within the school environment that exerts any form of violence against a child.</i>
<i>If you do not play with me, I will hit you.</i>
<i>"You are fat".</i>
<i>Any kind of expression (verbal, physical, using gestures or facial expression) of one person towards another that will make the recipient feel insecurity.</i>
<i>To terrify weaker or sensitive children with actions or words within school environment.</i>
<i>Verbal or physical maltreatment.</i>
<i>A child becomes a target of bullying of a group of children.</i>
<i>To taunt a child or some children.</i>
<i>To hit a classmate.</i>
<i>Actions or words within school environment by older children or classmates.</i>
<i>To scare children at the restroom, to push them, steal their food and property.</i>
<i>The maltreatment of a physically and psychologically weak child by a stronger child.</i>
<i>A child is inflicting fear or feelings of inferiority upon a child, verbally or by his/her actions.</i>
<i>Marginalization, verbal violence, emotional blackmail.</i>
<i>Violence with words or actions and humiliation of a group of children.</i>
<i>A child is afraid of expressing his opinion or of reporting his problem, because he/she worries that they will not believe him and they will accuse him of something.</i>
<i>A child becomes a target of victimization and is marginalized.</i>
<i>Terrorism.</i>
<i>Any kind of a "clique" that excludes other children from being integrated and taunts them for the "disadvantages" of other children according to their opinion.</i>
<i>To eat their food without giving it voluntarily.</i>
<i>A verbal threat or physical violence by an older or stronger child or a group of children against another child. In addition, a threat by a teacher who compares children with their classmates highlighting their defects and not their positive traits.</i>
<i>Any form of violence, a simple act of hitting.</i>
<i>Young and weak children are afraid of older children, "not always". They are more afraid of brash children.</i>
<i>Older children or spoilt, hit weak children or steal their property or destroy them.</i>
<i>A boy from our neighborhood was telling my daughter that if she did not give her a lollipop, he would not play with her, and he would kick her, etc.</i>
<i>Bullying is when somebody exerts physical or psychological violence on another person.</i>
<i>Bullying is the use of violence against students and their peers, with the aim of causing pain or discomfort. I do not have any incident to describe.</i>

<i>The phenomenon of bullying is one of the worst phenomena in my opinion. Nowadays, this phenomenon is one of the most common, a very short example is that children with mental or physical disabilities that are being subjected to bullying by children who do not have such a problem.</i>
<i>When somebody threatens and lays down the rules for something.</i>
<i>Any form of physical or psychological violence.</i>
<i>Bullying is a phenomenon that emerges in school settings among peers. Violence or aggressive behaviour is displayed against weak children that cannot defend themselves.</i>

Given the global upsurge of the phenomenon, prevention, intervention as well as the development and implementation of anti-bullying programs are crucial issues for counteracting bullying. The results of the present research, focusing on the aforementioned dimensions, are summarized below in Tables 3, 4 and 5 respectively.

Finally, with regard to the open-ended “How would you define school bullying? Please describe briefly an example”, parents gave the following answers that are summarized in Table 6.

CONCLUSION

As can be deduced from the presentation, analysis and interpretation of the above-mentioned results, most parents generally regard school bullying as a “phenomenon” that makes child victims feel bad. However, there were many parents who, having a vague picture of school bullying, indirectly defined the phenomenon by citing an example of violence that their children experienced. Also, many parents conceptualize school bullying as any form of violence within the school environment that can offend or hurt a child. Almost all parents are dissatisfied with this phenomenon, incriminating and criticizing teachers for its occurrence at school.

As it emerges from the survey, the phenomenon of school bullying is a major concern for parents of preschool children who are willing to participate in preventing this phenomenon. Most parents state that they are aware of the upsurge of school bullying despite the fact that they do not have a clear picture of its incidence in their child’s school unit. However, most parents believe that preventing, tackling and developing-implementing school bullying prevention programs within school environment could effectively contribute towards the desired direction.

Some of the findings of this study are consistent with related research on parents’ views on the phenomenon of school bullying among preschool-aged children. The survey of Karga (2013) for example, has shown that school bullying according to parents (a) is a rapidly growing phenomenon and is a very serious problem even in countries with a small population and a medium socio-economic level such as Greece and others, (b) it is considered to be a normal phenomenon because it is part of the development of children and (c) it is considered non-harmful within school environment, because it increases the range of real negative social experiences by teaching many children not to be so sensitive to the pressures of peers, situations that will certainly encounter in later life.

In contrast to previous research, parents believe that school bullying is a very dangerous and not a didactic phenomenon that needs to be dealt with effectively by both parents and educators, without the use of strict practices and physical punishment.

Finally, as can be seen from this survey, most parents believe that the most frequent attacks at the nursery school and kindergarten occur at breaks. The offenders are mostly boys who act individually or in very small groups, completing their aggression cycle against a child within 2 weeks.

Despite the limitations of this research, researchers were given the opportunity to study and record clearly some of the trends that emerge regarding the perceptions of parents. The study of these trends could contribute to some extent to the fullest understanding, prevention and counteracting of school bullying at the extremely sensitive preschool age.

ABOUT THE AUTHORS

Eleni N. Nikolaou is a Lecturer at the Department of Sciences of Preschool Education and Educational Design at the University of the Aegean in Greece. She holds a Ph.D. in Psychology from the same academic department (2005). She graduated with a Master's Degree (Msc) in Counselling Psychology from City University, London, UK (1999). She received her Bachelor's Degree in Psychology from the University of Crete in Greece (1996). Dr. Nikolaou has an extensive professional experience in counselling. She has worked for almost fifteen

consequently years in a counselling and mental health service for children and adolescents in Greece. Her research interests include school counselling, counselling and special education, child behavior problems, school bullying, social development of children, social anxiety, social competence and shy behavior, emotional intelligence, issues of developmental psychopathology. She is also a reviewer in Greek and international peer-reviewed Journals.

Panagiotis J. Stamatis, Ph.D., is an Associate Professor of Communication Education at the Department of Sciences of Preschool Education and Educational Design at the University of the Aegean in Greece. Dr. Stamatis teaches the subject “Pedagogical Communication in Preschool and Early Primary School Education”. His research and instructional interests are in Communication Pedagogy, Communication Development and Communication Instruction in school and family environments specialized for undergraduate, postgraduate and doctoral degrees. He is author, co-author, reviewer and editorial member in international journals. He was awarded by the Greek (local and national) authorities and institutions for his writings and for his social contribution. For many years, he participated in social activities as a President or/and a Member of Municipal Organisms related to Education and Culture. Dr. Stamatis has served as President or/and Member of many Committees, Associations, Libraries or other services regulated by the local Municipal Authorities or/and supervised by the Greek Ministry of Education, Research and Religious Affairs.

de Pediatría (CEAMI-P-INP), Ciudad de México, México

ABSTRACT

Violence has been part of the lives of individuals. The term “bullying or peer abuse” is currently used to designate violence among children of about the same age at schools. It is characterized by the presence of an intentionally repeated and unjustified aggressive behavior of a child or group of children towards another with the objective of inflicting physical or emotional harm to the victim. In developed countries, the prevalence is very high. Usually, physical abuse is common among boys and young men while discrimination and psychological abuse are more frequent among girls and young women. In recent years, there has emerged a new form of bullying known as “cyberbullying.” This form of bullying is defined as an aggressive act by a student or group of students using electronic devices.

Customarily, the actors in play in the issue of bullying are constituted by the provokers, the aggressor, the victim, the observers or witnesses and the authorities. Usually, the authorities are the last to know about the situation and this normally happens when the victim’s parent raise their voice or file in a report.

Apart from the physical harm, victims of bullying may suffer different associated pathologies such as depression and suicidal attempts. For this reason, the development of a program of actions involving the participation of the school authorities, the students, parents and the society in general directed to the prevention of the phenomenon through communication with the responsible authorities, students supervision within the classrooms, the school environment and their immediate surroundings, and the psychological therapy of the victims if the need be.

*Corresponding Author’s Email: juarezol@yahoo.com.

In this chapter, we review all aspects of bullying, bringing into limelight the actors in play, the sites of occurrence, its modalities, and the basic and extreme clinical characteristics as well as the curative and preventive interventions necessary to curb this phenomenon.

Keywords: aggressive children, discrimination, peer abuse, physical abuse, violence

INTRODUCTION

Violence has been part of the lives of individuals, their communities and population settlements since the record of human existence. Within the society, it is used as a way to impose and exercise power on others and to bring order. By definition, violence is a deliberate use of physical force or power as a threat either on oneself, another person, a group of people or a community. The consequences on the victim can be injuries of varying severity, alteration on his/her physical and emotional development, psychological damage and even death [1-6].

Violence in the school among children of about the same age is known as “bullying” or peer abuse. This problem is characterized by the presence of an intentionally repeated and unjustified aggressive behavior of a child to physically or emotionally harm a classmate or schoolmate with less power or strength either in the classroom or in other areas of the school. Because of its worldwide frequency, peer abuse is regarded as a public health problem [7-9].

The origin of the study of this type of child abuse is dated back to 1973 when Dan Olweus started to study it in Norway. Olweus was concerned to know why some adolescents had committed suicide. He discovered that such adolescents were people who had suffered bullying during their childhood. In the decade of the 1980, the problem was studied in some European countries, North America and Japan, as well as in Australia. The clinical, social and economic results of those studies were very similar to what were initially described [10-11].

On analyzing the frequency of the problem in 40 countries in North America and Europe, it was found that this varies from 8.6% to 45.2% in boys and from 4.8% to 35.8% in girls [12-15].

RECENT STUDIES

A report of the Swedish National Agency for Education established that 9% of 4th and 6th grade students, ages 10 to 12, and 3% of 7th to 9th grades with ages ranging from 13 to 15 years have been assaulted by other students [16]. In some places in China, the frequency ranges from 2% to 66% and in Hong Kong, it is from 24% to 50% [17].

Recently in the Czech Republic, there has been a clear decline in reported cases from 1994 to 2014. It is pointed out that probably this change was secondary to the modification in the political regime of this country, the establishment of a school program, the preventive action of the police and to a clearer understanding of the problem by the society [18].

In recent years, a new form of bullying problem known as “cyberbullying” has emerged and is defined as an aggressive act by a student or group of students using electronic devices. The evolution of this modality of bullying and its consequences on the victims have increased and it is changing in line with the advances in electronic devices [19-24].

In Mexico, “bullying” became known through some research works carried out in primary schools in the cities of Guadalajara, Colima and Mexico [25-27]. Considering that in Mexico, 24% of the children and adolescent population is in school age, the distribution of bullying is 92% in public schools and the remainder in private schools.

In a pilot study of 485 students (51% males and 49% females, aged 11 to 16) conducted by the Comprehensive Care and Abused Children Clinic of National Institute of Pediatrics (CCACC-NIP) in a secondary school located in Coyoacan Local Government Area, Mexico city, it was found that:

- There was “bullying” in 30% of the students.
- The behavioral distribution of the studied population was aggressive in 11%, provokers in 11%, victims in 8.4% and the rest were observers.
- Aggression types were verbal in 53%, physical in 20%, social in 18% and others 9%.
- The places where the phenomenon occurred were mainly in the classroom in 62% and in the school yard in 18%.
- The reported frequency of aggression was one to two acts per week in 30%.
- The physical aggression predominated in boys and psychological in girls (data not published).

This behavior of the victims is very similar to the report of research works performed in other countries [28-29].

Violence experienced in the schools or in their classrooms is a situation that has always happened and traditionally it is regarded as something normal. The perpetuation of this type of negative conducts is simply because it is often a common treatment between students and teachers [30].

ACTORS IN BULLYING

In this type of abuse (bullying or peer abuse), there are always three actors:

The Victim

The victim is a minor of any sex with some physical, racial, emotional or religious characteristics that make him or her appear weaker than and different from the aggressor. These peculiarities can be skin color, short stature, very thin or fat, use of eye lens, shyness or timid, insecure and unsociable.

In a series of 35,013,000 students studied in the USA, there was no significant difference in the gender (boys 12,862,000 and girls 12,151,000) of the victims however; the aggression was slightly more frequent in girls [12, 31-33].

The behavior of the victim changes remarkably as a consequence of the type of aggression, its frequency and severity. Usually, the victim suddenly becomes sad and shy, loses some personal or school objects without justification and unlike before, asks money from the parents.

These changes should points of alert to the parents, the teachers, the school authorities and the classmates or peers; however, most adults very often say, “it also happened to me” or “it is a good experience for him or her to learn to defend himself/herself from others” or “if we intervene, in the school, they will attack him/her more” or even say, “nothing will happen to him/her” [34].

Finally, we must consider in these cases the racial difference that exists in some countries of the world. In the US, the problem has been shown to be more common in African-American adolescents than in Asian and Latin adolescents [35].

The Aggressor

The aggressor is the minor who carries out the aggression or induces it and obviously he or she is physically and emotionally superior to the victim. The aggression could be physical, emotional, intellectual or economic. Usually, the aggressor is characterized by lacking the sense of guilt and by having impulsive and aggressive temper with uncontrolled anger. Frequently they are people who come from homes that are characterized by their high aggressiveness, violence and lack of love among the family members as well as an absence of operating rules of conducts or norms in the family and hence, they cannot control their temper. In most of the cases, they are bad students and have no interest in studies. Despite these characteristics, a high percentage of them have a history of living or suffering from family violence or being physically, emotionally or sexually abused in their homes.

Usually, the aggressor is surrounded by other school mates that support him and in occasions, these supporters carry out the aggression on his or her behalf for fear of or to please the aggressor and in this way avoid being a victim of the phenomenon. Literature report shows that the aggressor enjoys the grief of the aggravated partner (60%) and that he or she is able to inflict pain regardless of the suffering of the victim, while 65% of them do it in order to “demonstrate their power and strength” over other school mates.

Boys and young men generally perpetrate physical abuse while girls and women deal with discrimination and psychological abuse.

An English study showed large differences between women victims of bullying in England with Pakistan and Caribbean women being the most assaulted when compared with women from other ethnic groups [36].

It should be emphasized that the most aspect of this situation is that, in all likelihood, the aggressor does not know the short, medium and long term consequences of his or her attacks on the child or the partners and these could at times be lethal and may, in part, explain the high level of juvenile suicide [37-38].

On the hand, the influence exerted by various situations or actions of the actors in some societies of the world must be born in mind. For instance, it is very evident that high consumption of alcohol and marijuana as well as the location of the school plays a vital role in this. If the school is located in a poor neighborhood and with a high level of delinquency, this will undoubtedly exert an influence in this situation [39-42].

The Witnesses

They are usually schoolmates of almost the same age and sex who witness the aggression without doing something about it due to fear or inability to stop it. Nevertheless, sometimes some of the witnesses may brave it and go to the teacher to inform him what is happening or talk about it at home and ask their parents for active and effective intervention with the school authorities. Frequently, the intervention of these adults is very minimal. It is also likely that the observer students are unaware of the consequences and the severity of the problem in the short, medium and long term.

It has been established that the passive reaction of the observer students may be associated with a low moral level and inability to defend themselves. Other factors may be the existing empathy with the other actors, inability to see and consider the negative consequences of “bullying” and lack of moral disagreement with the subject [43-45].

It may be interesting to point out a characteristic event that happened for many years in Mexico which lies on the tolerance of school authorities, teachers and students for actions known as “hazing”. This action or harassment was usually towards newly admitted students in secondary and high schools or in colleges or universities. In this event, newly admitted adolescent students were the victims of physical, emotional or moral aggressions which though did not put their physical integrity at risk but affected their emotions and rights. Traditionally, this action was considered as a celebration of welcome to the newly admitted students to a school. Presently, such activities have almost disappeared from national schools.

SITE OF OCCURRENCE OF THE PHENOMENON

The problem of “bullying” is usually staged inside the schools, especially in the classrooms, hallways, staircases and in lesser degree in the yards, bathrooms, cafeteria, on the streets near the schools or in the school buses. The type of school, its academic quality and the neighborhood in which it is located should be considered when the school is being evaluated.

In an analysis of 49,698,000 public and private schools in the United States, it was shown that “bullying” occurred more frequently in private schools and even more in non-Catholic private schools [12, 46-47].

In the face of this knowledge, it must be emphasized that the primary function of the school authorities and the teachers is to detect and to directly or indirectly intervene, as soon as they are aware of “bullying” situation.

MODALITIES OF BULLYING

Bullying types can be diverse and regularly depend on the age of the victims and the school grade of the actors. On these bases, we can distinguish the following types of bullying:

- Physical abuse. It is more often observed in primary schools and less frequent in middle and upper schools (junior and senior high schools and the university). The type of aggression normally observed in this abuse is characterized by injuries caused by

blows, pinching, pushing, and damage to various personal objects of the victim, theft of personal school materials and demand of money. The victims can be threatened with white weapons or firearms. In this modality, in addition to the aggressor, there are “guards or beaters” who carry out the act of intimidation.

- Psychological, moral and sexual abuse. Usually, this type occurs inside secondary schools or higher education. The main characteristics of this modality of abuse are: spreading malicious rumors about the victim, insults, prohibit the victim from integrating in the school dynamics or extreme isolation. An associated modality to the above is the incorrect use of social webs known as “cyberbullying.” This medium propitiates the staging of aggressive attacks through mockery, threats and discredit.
- Sexual abuse is characterized by harassment, induction to sex, touching or sexting which is the sending of sexual materials by electronic means.
- Homophobic bullying or gay bashing. It refers to any kind of psychological, physical and moral damage for having or pretending to have a different sexual orientation.

Table 1. Basic facts of bullying

a) There is a clear imbalance in physical, emotional, intellectual or economic between victims and perpetrators.
b) The phenomenon is frequent and repeated.
c) There is little or no peer intervention to detain the action.
d) There is little intervention of the parents or little likelihood that they are attended by the school authorities and teachers.
e) Usually, the teachers are unaware or the last to know that the phenomenon occurs.
f) School authorities generally do not accept or bluntly negate the existence of the problem. This situation is more common in private schools.

Table 2. Clinical characteristics of bullying

a) The child attacked offers little or no resistance to the aggression due to fear or unequal power with the perpetrator.
b) There is intentionality of the aggressor. The purpose of the actions is to physically and emotionally harm the victim and to inspire fear, distress and physical or emotional suffering. Apparently in this way, the aggressor enjoys or derives pleasure.
c) The aggressor ignores the physical and emotional development of the victim as well as the severity of the long-term consequences.
d) The classmates have a passive attitude towards the existence of the problem.
e) The teacher and the school authorities usually do not want to get involved in the problem for the mere fact that they are ignorant of how to resolve the situation, afraid of losing the enrollment of the problematic student and not willing or wanting to face the parents of the aggressor student.

The basic characteristics of bullying are presented in Table 1 and the clinical characteristics in Table 2 [48-51].

There are other manifestations that the minor refers to and that parents and teachers should know and consider. In this way, they can establish the suspicion of abuse among peers or confirm their existence (Table 3) [52].

Table 3. Behavior of the victim of bullying

a) The child reports that he is being assaulted by one or more of his classmates. b) The child has problem making friends and greater difficulty in relating to peers. c) A sudden drop in school performance is observed. d) The victim tells the parents that he/she does not want to attend school and manifests that he/she is suffering various discomfort, usually subjective, such as abdominal pain, headache, nausea, diarrhea, feeling tired, etc. e) Suddenly, he/she requests to be changed from school on flimsy reasons that he/she does not understand the teachers, because the courses are more difficult and because he/she has no friends. f) Sometimes, even if he/she changes school, the child or the adolescent says that he/she no longer want to go to the new school or continue schooling and that probably he/she wants to work, play sports or rest.
--

EXTREME ACTIONS

It is very probable that the aggressor students or classmates, the teachers, the school authorities and parents do not know the extreme behaviors of the victims of “bullying.” In Table 4, we present the most important of these extreme behaviors [53-56].

Table 4. Extreme clinical aspects of the victim of bullying

a) On quitting school, the child may begin the consumption of licit and illicit drugs. b) The child may begin to go with groups of youths that do not study or work and begins with criminal activities. c) The child may fall into a state of major depression. d) A state of psychosis can become evident. e) The child thinks in suicide attempts and may succeed in carrying it out. f) The child can decide to injure the schoolmates with white arm or firearm in his/her possession without the permission of the parents.
--

As previously pointed out, the behavior of the child or adolescent should alert the parents, the teachers, the school authorities, the pediatric physicians and the family members to intervene immediately, dynamically and effectively.

INTERVENTION OF THE PARENTS

Initially, parents must assume a real responsibility and begin a talk with the child to know what is happening to him/her. The following action must be carried out:

- 1) If parents become aware that their child has problems with one or more of his/her classmates, they should listen and believe the child, go to the school to speak with the teacher, the higher authorities of the school and with the parents of the child shown as the aggressor.
- 2) The parents should take the child to be checked by a pediatrician or family doctor to rule out a disease that explains the clinical manifestations already noted. The doctor must issue a certificate of physical and emotional health. If necessary, the physician should refer the child to a mental health professional (psychiatrist or psychologist).
- 3) The teacher and the school authorities should be involved in investigating the problem and listen to the parents on both sides. Often, the parents of the aggressor child are violent, with history of different addictions and generally do not accept their child's actual behavior.
- 4) When the victim presents data suggestive of important alteration in his/her self-esteem, depression, anxiety or distress, he/she and the family should be attended by a mental health professional.
- 5) The mental health professional should analyze and try to resolve the situations of family violence, different addictions in any of the progenitors, the existence of any modality of child abuse and attend the problem of school dropout as well as possible contact with illicit drugs and organized crime.
- 6) At school, a general program should be developed to explain to all students what bullying is and its consequences.
- 7) School authorities should make an effective decision in the event that the parents of the aggressor child refuse to accept the measures indicated at school. Certainly in private schools, this action is very difficult to carry out because there is a possibility that the parents remove the child from the school on knowing about the problem and therefore the school loses the enrollment and hence the corresponding income.

What Should Be Done Once the Diagnosis Is Established?

Without doubt, all the actors in this problem need to have complete information on the subject and the school must have a group of professionals trained to resolve the physical, emotional and legal situations.

In all cases, adults should carry out the following actions:

- a) The victim must be attended by the family and teachers with affection, interest and knowledge of the cause so as to recover his/her self-esteem, social security and attachment to school. The existence of depression, anxiety and distress requires (in

some cases) the intervention of a psychiatrist or psychologist, qualified in the subject, to attend and resolve the situation of the child or adolescent. The parents and the pediatricians should be attentive to the progress achieved on the emotional and physical condition of the child.

- b) As a personal action, the victim should try to improve his/her physical aspect by engaging in sports and in correct form, eat suitable diet.
- c) Another fundamental situation arises from the need for the aggressor child or adolescent to receive the necessary family and professional support to treat some psychological pathology aimed at avoiding that he/she continues having or showing arrogant attitude and with that, avoid that the child direct his/ her interest towards the consumption of licit and illicit drugs, engaging with gangs, delinquents etc.

In the face of bullying, the parents of the victim and the perpetrator, the teachers and the school authorities must understand and accept that these children have a problem and that it must be effectively attended in order to gain their trust. Channeling him/her towards practicing a sport, artistic activities (playing guitar, piano and drum or enrolling him/her in a choir, musical band or theater group) or participating in social support activities to the community can be extremely useful actions.

School officials should understand that the parents of both the victim and the aggressor can develop frustration when they do not receive specific and adequate attention on the problem that their children are experiencing. Therefore, we must emphasize on the development of a two-way intervention to confront the problems inherent in bullying [57].

The existence of an emotional disorder such as autism or attention deficit hyper-reactivity disorder (ADHD) must be medically treated depending on the severity of the problem [58].

PREVENTIVE PROGRAM

We must be aware that measures to combat bullying through punishment, sanctioning and lawsuit do not seem to be the ideal strategy.

Several programs have been developed and published for the prevention of this problem. Nevertheless, few indicate positive results because the socio-cultural and economic differences of the people are a major barrier [59-60].

Faced with this global reality, development and implementation of practical and low-cost programs for the prevention of bullying is imperative. It is important that such program should consider boys and girls, adolescents, parents, teachers and school authorities.

At the CEAMI center of the National Institute of Pediatrics, a comprehensive care project has been designed to prevent bullying. It proposes the development of a strategy with transversal axis that, though involves all the actors who take part in the same, suggests considering in a primordial way the students, even when the basic actions fall on the school authorities. This proposal differs from the traditional vertical action that begins with the school administrative authorities and ends with the students – people who are not given the importance they deserve.

Obviously, to be successful with this program or similar programs; an active, dynamic and consensual participation of all the actors living and coexisting in an educational establishment is required. It is also desirable that the implementation of any program considers and involves primary and higher educational institutes, both officials and privates.

BASIC ACTIONS

Although the initiative begins almost always with the school staff, the novelty proposed is the primordial intervention of the students as well as the thinking and actions of the parents. In this way, it is insisted that the parents and children develop an active and purposeful intervention.

Initial Activity

Obviously, the initial action must fall, as already mentioned, on the administrative authorities of the school. These authorities and the teachers must propose and conduct an initial interview with the parents and members of the student society (if it exists) to present the general idea of the project.

The people involved are:

- a) Students
- b) Parents
- c) Educators and teachers
- d) Officials of the school.

The materials required are:

- a) Handbook of Procedures for the Prevention of Bullying. Every school must have this handbook which must contain basic aspects of the subject.
- b) Handbook of Values. Also every school and colleges must have this kind of handbook that reiterates and emphasizes the values of the school.
- c) Academic Program. The schools must have academic program which contains the basic theme of Civics.

SPECIFIC ACTIONS

- 1) All the school staff – the principal, the teachers, the administrative staffs and the quartermaster - must know and analyze the “The Handbook of Procedures for the Prevention of Bullying” before the beginning of each school year.
- 2) The handbook of Procedures for the Prevention of Bullying will be given to parents or guardians upon enrollment of the students and before the beginning of the school year.

- 3) At the beginning of the school year, the administrative authorities will hold a meeting with the tutors, parents and some senior students to explain the strategy that has been designed to detect and prevent bullying, as well as the importance of engaging all the people involved to participate actively.
- 4) Parents must sign an internal register testifying that they have received, read and totally understood the “The handbook of Procedures for the Prevention of Bullying.”
- 5) The handbook would establish the participation and commitment that the following people acquire:
 - School authorities
 - Tutors
 - Parents
 - Students

PROCEDURE

Students

A. Actions of the Administrative Authority

- 1) All members must have and know the Handbook of Procedure for prevention of Bullying.
- 2) A basic program of civics and values will be implemented in all groups in the school. The teachers may make a brief interview on the impact achieved in the students and in the families. Value information must be included as a subject in the school curricula. Its basic focus is to reach the projection of the best of every human being incorporated in the society.
- 3) Complaints or expressions of violence among peers, whether verbal, written and electronic or by direct observation is detected and analyzed. In addition, strategies will be implemented to resolve them and in this way, prevent the problem from increasing.
- 4) Direct and permanent contact is maintained with the teachers, parents and students following an established schedule. The academic board must include a section that evaluates the strategies outlined for the healthy coexistence of students, analyzes the strengths and weaknesses of the program and adjusts the action plans according to the results obtained during the period under review.
- 5) It is proposed that the administrative authority of the school names two teachers who will anonymously develop the supervision of the students. This function could be rotating and will last the period the school authority considers pertinent.
- 6) The naming of two students from each group of higher grades of basic education (4th, 5th and 6th) and senior high (7th, 8th and 9th) and their coexistence should be supervised

to ensure that they carry out an anonymous monitoring. These students must be changed in a pre-established period.

- 7) Two parents will be requested to make analysis of the comments of their children, peers, other students and parents.

B. Actions of School Teachers

- 1) The teachers should emphasize with their students the meaning and the consequences of bullying and keep a close watch on the behavior of the students, especially in the class room, and of course, the spaces the students occupy in the recess and breaks should not be neglected. In this period, situations of violence should be monitored because the students think that they are less watched. Other areas to monitor in addition to the yard and playground are mainly the stairs, restrooms and school buses.
- 2) The teachers should listen to students' opinions on peer behavior. This constitutes a tool for data collection for making proposals that would help to establish and maintain healthy students' coexistence. The anonymity of such opinions should be strictly maintained.
- 3) Also, the teachers should constantly reinforce the concepts established in the Handbook of Procedures for the Prevention of Bullying.
- 4) With the periodicity established in the program, the teachers should emphasize and reiterate compliance with the Program of values and Civics of the school.
- 5) The teachers will maintain an environment of healthy coexistence through each and every one of the activities, emphasizing the positives of the group and helping to create in every one a healthy self-esteem.
- 6) The teachers will formulate and encourage strategies that will permit the students to express their feelings through painting, music, dance and sports. The aim is to detect the emotional situations which the students of each group are passing through.

C. Actions of the Teachers Assigned to Surveillance

The surveillance teachers will detect, register and notify (at a pre-established periodicity) to the administrative authority of the events and results of their intervention.

D. Actions of the Students

- 1) The selected students will receive a talk supported with pictures to explain the importance of knowing the risks of bullying among school children and the need to develop a harmonious coexistence within a framework of respect and responsibility.
- 2) They should maintain constant contact with the surveillance teachers and the school administrative authorities.
- 3) They will actively be part of permanent campaigns that address and encourage ethical values essential for coexistence among peers.

E. Parents

- 1) The selected parents will receive a talk supported with pictures to explain the importance of knowing the risks of bullying and the need to develop a harmonious coexistence within a framework of respect and responsibility in the school.
- 2) They should maintain constant contact with the surveillance teachers and the school administrative authorities.
- 3) They will actively participate in permanent campaigns that address and encourage ethical values essential for coexistence among peers.

Considering the consequences of bullying which can be observed in the victim and the perpetrators, a maximum and integral effort must be made to promote the development of socio-personal skills, the teaching of values and individual attention to the actors in the conflict.

It should be borne in mind that any innovative change generates rejection and criticism, but it is better to face them than doing nothing. Remember that if we fail in this action, the future of the school children will be very somber and they do not deserve it [61-63].

FINAL CONSIDERATIONS AND STRATEGIES

Parents should be attentive to the presence of this phenomenon, whether their child is the victim or the perpetrator. Also, it should be mentioned that the family is fundamental in the job of instilling principles and values that will make it possible to avoid and, sometimes, to confront bullying.

Remember that the family influences the socio-affective development of the children, since the models, values, norms, roles and abilities are learned during this period of life and are related to handling and resolving conflicts principally with the social and adaptive abilities, with the pro-social behaviors and with the emotional regulation [64].

On the other hand, there is evidence that adults who perpetrate bullying in their childhood develop family violence.

According to the proposals described, it will be possible to identify, stop and prevent school, environmental and family violence. For that, it is necessary to:

- 1) Involve the parents, teachers, physicians and families.
- 2) Promote the development of protocols of detection and attention. To propose cycles of conferences on violence, licit and illicit drug consumption, as well as human upbringing.
- 3) Insist on the children and the adolescents about the need to notify the school authorities or their parents of the existence of the problem.
- 4) Prohibit "hazing."
- 5) It is essential to eliminate violent and sexist content in the announcement sites.
- 6) Permission to use cellphones, cameras and devices of various natures must be controlled. These objects will only be allowed for academic activities.

Chapter 130

CONCEPTUALIZATION OF ANTI-BULLYING STRATEGIES: KEY ASPECTS IN EVERY CURRICULUM AREA

N. P. Mudzielwana, PhD

Department of Early Childhood Education,
University of Venda, Limpopo Province, South Africa

ABSTRACT

This is a concept chapter and it argues that learners should be taught anti-bullying strategies in schools. Bullying is the use of force, threat, or coercion to abuse, intimidate, or aggressively dominate others and can be another obstacle to learners' academic success. School should be a place to learn and grow and not to be intimidated and harassed or brutalized. It is suggested that by putting a stop on bullying, learners can learn in an environment which is conducive to learning and can learn how to be good citizens. Teaching anti-bullying strategies well is a key aspect of developing learners' physical and emotional health. In line with social cognitive theory, bullying is an anti-social whereby learners are subjected to threats and abuse. Challenges of such conceptualization and implementation of anti-bullying strategies are numerous. This conceptual paper examines strategies used to teach anti-bullying in schools. The chapter reviews literature on the philosophical concept of bullying strategies. The chapter analyzes the significant usage of anti-bullying strategies as prominent strategies in teaching bullying as informed by conceptual and theoretical frameworks of cognitive and metacognitive theories which have been proved by researchers in teaching contexts. Because it is a concept paper, no empirical investigation was undertaken. The chapter is constructed using a number of data bases in fields such as sociology, policies, early childhood, psychology and newspaper commentators was used to examine literature on anti-bullying. According to Burger, Christoph; Strohmeier, Dagmar; Spröber, Nina; Bauman, Sheri; Rigby, Ken (2015) bullying may be defined as a subcategory of aggressive behavior characterized by the following three minimum criteria: (1) hostile intent, (2) imbalance of power, and (3) repetition over a period of time. Bullying may thus be defined as the activity of repeated, aggressive behavior intended to hurt another individual, physically, mentally or emotionally.

Keywords: socio cognitive theory, bullying, strategies, policies, teaching

INTRODUCTION PERSPECTIVE

This is a concept paper which discussed what literature says about bullying and what strategies can be taken to reduce bullying in schools.

While bullying is a pervasive problem in many schools, schools can take specific steps to improve the school climate and encourage positive interactions designed to reduce or prevent bullying.

Bullying may be the most frequent form of school violence (Nansel et al., 2001). Surveys consistently indicate that almost one-quarter of all students experience hurtful interactions with peers on a monthly or daily basis (Dinkes, Cataldi, & Lin-Kelly, 2007).

Bullying is a significant problem that needs to be reduced, and one way to do this is by intervening directly with the bully perpetrators with the goal to help these individuals change their cognitive and social behaviors that underlie their bullying perpetration.

Although this is a concept paper, the following are some of the recent cases of bullying that is happening in schools.

Africa Check, Published: 30th January 2017 09:15 (GMT) Reality check: Are SA pupils the ‘most bullied’ in the world?

Comments 1 South African pupils are “the most bullied kids in the world,” according to the country’s education minister. The Africa Check team sharpened their pencils to verify the claim. Researched by Gopolang Makou & Julie Bourdin.

Trends in International Mathematics and Science Study (TIMSS) from (2015) South African Grade 9 pupils are reported the third highest incidence of bullying out of 38 countries, behind Botswana and Thailand. The majority of Grade 9 pupils (47%) reported being bullied “about monthly” and 17% reported being bullied “about weekly.”

Cape Argus 28 February 2017. A 13-year-old boy will have to undergo surgery on his face, after a bully beat him up. Cape Town – After being bullied at his primary school in Parow, a 13-year-old boy will have to undergo expensive surgery to repair the damage to his face.

According to the WCED, 81 cases of bullying were reported last year. “Many schools deal with bullying in terms of their school code of conduct and do not necessarily report incidents to our Safe Schools Directorate,” Shelver said.

Marius Lotter, owner of Shido Fighting Systems in Centurion, said.

A simple push in the line is all it takes to initiate a cruel form of punishment that haunts hundreds of children in South Africa. Shocking as it may be, a survey conducted by consumer-insights company Pondering Panda found that 57% of children felt they had been victims of bullying at school. “This statistic is alarming and should be addressed by parents and all bodies involved in a child’s development.”

The latest statistics from the Progress in International Reading Literacy Study (PIRLS) showed that South Africa is the country with the highest bullying rate in the world for grade 4 pupils. Lotter saw this as an opportunity to develop a program for children where they could learn fighting techniques in a controlled and disciplined environment, while being taught that hand-to-hand combat is not the prime solution.

Researchers Hoover and Oliver (2008, p. 10)) stated “Bullying is always directed by a stronger student against a weaker one” (p. 10). The National Center for Educational Statistics (2015, p2) identified statistics relative to bullying incidents:

- One out of every four students (22%) report being bullied during the school year.
- 64 percent of children who were bullied did not report it; only 36 percent reported the bullying.
- The reasons for being bullied reported most often by students were looks (55%), body shape (37%), and race (16%).

THE PURPOSE OF THE CHAPTER

This conceptual paper is envisioned to classify and augment understanding of the strategies that can enhance anti-bullying in learners. Therefore, the probe questions for this paper are:

- How can various anti-bullying strategies be employed to enhance learners’ learning?
- How can various anti-bullying strategies enhance learners ‘learning?

METHODOLOGY

The methodology of the chapter is content analysis. Authoritative sources relevant to bullying in schools were selected and consulted. The reason of using content analysis is to investigate the topic through document analysis and scholarly documents. According to Leedy and Omrod (2005) content analysis identified specific characteristics of a body of material.

THE CONCEPTUAL FRAMEWORK

Bullying is a widespread problem that has significant deleterious effects on the physical, mental, and social health of youth. In a recent survey of over 30million U.S. students between the ages of 12 and 18, nearly 32 percent reported that they were bullied at school (US Department of Education 2011).

Bullying is a phenomenon that occurs in most societies around the world (Child Helpline International, 2012). On a global level, 48% of boys and 57% of girls state that they have been bullying victims (Child Helpline International, 2012). Bullying is a pervasive social problem that is believed to have affected about one-third of students in their lifetime (Cooper & Nickerson, 2013).

There is no universally accepted definition of the term bullying; however, a widely-cited and influential definition of bullying is that of Olweus (1993(p. 125): “a student is being bullied or victimized when he [sic] is exposed repeatedly and over time to negative actions on the part of one or more other students.”

Bullying may be defined as a subcategory of aggressive behavior characterized by the following three minimum criteria: (1) hostile intent, (2) imbalance of power, and (3) repetition over a period of time Burger, Christoph; Strohmeier, Dagmar; Spröber, Nina; Bauman, Sheri; Rigby, Ken (2015). Bullying may thus be defined as the activity of repeated, aggressive behavior intended to hurt another individual, physically, mentally or emotionally.

Bullying is a group process and the peer group dictates whether a bully can establish dominance (Salmivalli, 2010). Bullying is the use of force, threat, or coercion to abuse, intimidate, or aggressively dominate others. The behavior is often repeated and habitual. One essential prerequisite is the perception, by the bully or by others, of an imbalance of social or physical power, which distinguishes bullying from conflict (Juvonen, and Graham, 2014) Behaviors used to assert such domination can include verbal harassment or threat, physical assault or coercion, and such acts may be directed repeatedly towards particular targets. Rationalizations of such behavior sometimes include differences of social class, race, religion, gender, sexual orientation, appearance, behavior, body language, personality, reputation, lineage, strength, size, or ability (Nels, June 2001). If bullying is done by a group, it is called mobbing (Davenport; Schwartz and Elliott, 1999).

Literature (Cornell et al., 2013, p. 139) indicates that bullying is a chronic stressor which causes traumatic impacts on adolescent development, damages an individual's "self-concept and trust in others, and leads to avoidant behavior and social withdrawal."

Bullying is considered a pervasive social problem affecting schools and students, as well as often being associated with tragic outcomes such as suicide (Jimerson et al., 2010; Pepler & Craig, 2008; Smith, Pepler, & Rigby, 2004).

According to Cornell, Gregory, Huang and Fan, (2013) bullying may affects individuals regardless of gender, age, and nationality although the highest frequency of bullying occurs during middle school, while one out of four experienced teasing and harassment during the previous year.

Olweus says bullying occurs when a person is "exposed, repeatedly and over time, to negative actions on the part of one or more other persons." He says negative actions occur "when a person intentionally inflicts injury or discomfort upon another person, through physical contact, through words or in other ways." Individual bullying is usually characterized by a person behaving in a certain way to gain power over another person (Besag, 1989).

While there are various definitions of bullying (Smith, Cowie, Olafsson, & Liefhoghe, 2002; Polanin, Espelage, & Pigott, 2012), the Centers for Disease Control and Prevention and the U.S. Department of Education, along with a panel of researchers and practitioners, recently established the following definition:

"Bullying is any unwanted aggressive behavior(s) by a youth or group of youths who are not siblings or current dating partners that involves an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated. Bullying may inflict harm or distress on the targeted youth including physical, psychological, social, or educational harm (Gladden, Vivolo-Kantor, Hamburger, & Lumpkin, 2014, p. 7.)"

Characteristics of Bullying

Scholars identified three characteristics of bullying namely repetition, intent to harm, and power inequity.

Repetition

The majority of definitions emphasize bullying as repetitive behavior (Salmivalli & Nieminen, 2002). Doing so distinguishes bullying from single acts of aggression, and to call attention to how bullying not only leads to immediate harm and but also threat of future victimization.

Consequently, researchers started promoting the notion that victimization and bullying should be conceived as falling along a continuum (Goldsmid & Howie, 2014). Because of this, research on bullying in schools tends to measure bullying according to combined variables of frequency and different behaviors within a given span of time (Gregor, 2004).

Intent to Harm

Intent to harm is theoretically significant in defining bullying because it sets bullying apart from accidental, and thus unintended, harm (Anderson & Bushman, 2002). Although most definitions of bullying contain terms such as deliberate and intentional, in practice, the concept of intention is problematic (Anderson & Bushman, 2002). This is because it assumes adequate honesty and self-awareness on the part of the bully. However, it is crucial that bullying be distinguished from inadvertent harm, which is why it is necessary to keep this criterion.

Power Inequity

Power inequity can be physical, psychological, economic, or hierarchical (Connell & Farrington, 1996).

Types of Bullying

There are four general types of bullying namely, physical, verbal, social exclusion, and cyberbullying (Lehman, 2015).

Physical bullying is manifested through hitting, kicking, pinching, spitting, pushing, tripping, taking or breaking the victim's things, and making rude gestures, among others.

Physical bullying involves the use of physical force (Gladden et al., 2014) and includes behaviors such as hitting, kicking, punching, spitting, tripping, and pushing. All of these behaviors fall within the realm of "violence," and are not considered "bullying" if they occur only one time and without a perceived power imbalance. Thus, the key differences between physical bullying and school violence are that bullying involves an observed or perceived imbalance of power and is repeated or is highly likely to be repeated.

Verbal bullying refers to either spoken or written forms of bullying, including name calling, inappropriate sexual comments, abusive language, and threatening to cause harm.

Verbal bullying involves oral or written communication that causes harm to the targeted youth (Gladden et al., 2014) and includes name-calling, taunting, threatening words, notes, or gestures, and sexual comments.

Social bullying involves harming relationships or another person's reputation (Pabian & Vandebosch, 2016); therefore, it includes intentionally excluding someone from activities;

persuading other people not to be friends with the victim; spreading false rumors; and, shaming or embarrassing the victim in public.

Cyberbullying is perpetrated through the use of information or electronic technology, including mobile devices, computers, and social media through text messages, chat, and social networking sites like Facebook and Twitter (Carter & Wilson, 2015). The cyberbully can capture the attention of a larger audience to initiate their attack, which leaves the victim with minimal protection and escape (Mishna, Khoury-Kassabri, Gadalla, & Daciuk, 2012).

THEORETICAL FRAMEWORK

Theories are used to explain, understand, or predict phenomena (Dubin, 1978). Given the complexity of bullying behavior, this chapter is underpinned by theoretical frameworks that are typically utilized to understand and address bullying. Four theories namely, social capital theory, dominance theory, the theory of humiliation, and organizational culture theory. This will help to understand this phenomenon and to inform effective prevention and intervention strategies and programs and to better understand the motivations behind bullying behavior.

Social Capital Theory

Social capital refers to the benefits gained from social relationships (Putnam, 2000). Specifically, individuals form and invest in social relationships with the expectation of fulfilling goals and profiting from their interactions with others (Coleman, 1988; Lin, 2001). Putnam described the mutual benefit of social capital as the force that drives people to maintain social networks: “Social capital refers to features of social organization such as networks, norms, and social trust that facilitate coordination and cooperation for mutual benefit” (Putnam, 1995; p 67). Social capital can be categorized as either bonding social capital or bridging social capital. Bonding social capital consists of social ties (i.e., interpersonal relationships) between similar individuals who belong to a homogenous group that creates a feeling of cohesion and shared belonging, whereas bridging social capital consists of social ties with people outside the homogenous group that creates a wider social network (Beugelsdijk & Smulders, 2003; Putnam, 2000).

To sum up, in social capital theories, both individuals and groups benefit from the resources of information, social influence, social credentials, and reinforcement of self-worth that social ties provide.

Dominance Theory

Social Dominance theory (SDT; Sidanius & Pratto, 1999) and dominance theory (Long & Pellegrini, 2003) provide insight into the bullying dynamic. Both theories indicate that youth bully one another in their attempts to gain group and individual-levels of social dominance, and then maintain their social status through ongoing bullying. In other words, bullying perpetration is used as means of establishing and maintaining dominance.

SDT focuses on group-based social hierarchies whereas dominance theory centers on individual-based social hierarchies. The fundamental tenant of SDT argues that all societies consist of group based social hierarchies that are based on gender (e.g., males have more power than females), age (e.g., adults have more power than children), and an arbitrary.

The Theory of Humiliation

Humiliation is “excessive overt derogation” that occurs when a more powerful individual publicly reveals the inadequacies of a weaker victim, who feels the treatment is unjustified (Jackson, 1999, p. 2). The concept of humiliation is distinct from shame. An individual can shame himself or herself, whereas humiliation requires action from an outside agent who engenders feelings of powerlessness in the victim (Hartling & Luchetta, 1999; Klein, 1991). Further, shame results in an internal feeling of inadequacy and embarrassment, whereas humiliation often causes anger towards the perpetrator and the desire for retaliation (Jackson, 1999). Conversely, the rage generated by humiliation can also be turned inwards in the form of depression (Lindner, 2007). These emotional reactions are quite common for victims after bullying incidents.

Humiliation involves “putting down and holding down” (Lindner, 2006, p. xi) and has such intense power that it is considered “the nuclear bomb of the emotions” (Lindner, 2006, p. 3). With the emergence of human rights and that all persons are deserving of dignity, humiliating another person became morally and ethically wrong (Lindner, 2001b). The basis for Lindner’s theory is the notion that all humans’ desire and deserve recognition and respect and humiliation violates this fundamental human right, resulting in eroded interpersonal relationships and disrupted social cohesion (Lindner, 2007). The humiliation dynamic involves three roles: humiliator (i.e., person who inflicts humiliation), victim (i.e., Bullies physically, verbally, or to a lower social status in an effort to establish power and witness - those who observe what happens and agree that it is disparagement).

Building on the work of Smith (2001), Lindner (2006, 2003) posited humiliation had four forms namely:

Conquest Humiliation — an individual uses conquest humiliation to force a former equal into a subordinate position. Conquest humiliation is a precursor to bullying because this form of humiliation establishes the power differential inherent in the bullying dynamic.

Reinforcement Humiliation is used to maintain the social hierarchy established by conquest humiliation.

Exclusion Humiliation is the most stringent form of humiliation and involves banishing victims altogether by exiling or killing them. In the realm of bullying, this form of humiliation would occur if the queen bee ensured that everyone in the class completely ignored and avoided her rival, perhaps until the rival left school or, in extreme situations, committed suicide.

The humiliation of being bullied violates the individual’s fundamental need for respect and recognition. Humiliation also undermines social standing, engendering the psychological pain of ostracism. Being bullied results in anger; this anger can be externalized as retaliation or internalized as depression. The outward expression of anger as retaliation can take the form of bullying, which fits with the description of the bully/victim as a person who is a victim of a bully, but also bullies others. In contrast, other victims internalize the humiliation and feel deep despair, which manifests as depression; this reaction leads to humiliation.

Organizational Culture Theory

Culture refers to shared values, beliefs, rituals, and customs (Deal & Kennedy, 1983). Although typically applied to ethnic or religious groups, the concept of culture also applies to organizations, and organizations have unique cultures that impact their success (Peters & Waterman, 1982). Indeed, the foundation of organizational culture theory is the notion that every organization has its own culture (Geertz, 1973). That is, organizational norms, beliefs, and behaviors impact how the organization functions and solves problems (Schein, 2010). The organizational culture in the context of a school is often referred to as the school culture or school climate. School culture is a broader concept than school climate (Schoen & Teddlie, 2008) and refers to “[A school’s] unwritten rules and traditions, norms, and expectations... that seems to permeate everything...” (Deal & Peterson, 2009, p. 2). School climate is more specific and refers to the “quality and character” of a school and includes elements such as the level of social, emotional, and physical safety; the presence of respectful behavior; an emphasis on the importance of learning; and collaboration between students, families, and educators (National School Climate Center, 2014). School culture and climate significantly impact rates of youth involvement in risky behaviors in the school setting. Accordingly, school culture and climate are associated with other social problems such as bullying.

A positive school culture and climate denote a feeling of safety and the presence of support; teachers are aware of their students’ needs, intervene in social disputes such as bullying, and encourage students to stand up for one another. Thus, a positive school climate is significantly associated with less bullying behavior (Lee & Song, 2012).

Anti-Bullying Strategies

Strategies to prevent bullying: what does literatures say?

The following are strategies:

- Creating a positive school environment as prevention
- Immediate, clear, and consistent intervention strategies
- Teachers as effective catalysts for bullying prevention
- Barriers to effective bullying prevention

Creating a Positive School Environment as Prevention

The research is clear that a major part of bullying prevention does not stem from specific techniques or strategies, but from establishing a school environment that is positive and supports students. Effective prevention and intervention strategies create a sense of accountability among all members of a school in creating and implementing an effective approach to dealing with harassment, intimidation, and bullying (Oneil et al., 2012). The creation of a positive school environment does not happen overnight, and it may be that one of the reasons that much of the research on bullying prevention programs has found these programs to be ineffective is because they are only looking at immediate, short terms changes in behavior. However, positive impacts of bullying programs do not occur over a short term period (three months), but take a longer time to take effect (one to five years). These programs

need time to penetrate a school culture and influence attitudes and behaviors (Smith et al., 2005).

Much of the research around effective bullying prevention centres on Jon Olweus, one of the few researchers to implement an effective anti-bullying program. Olweus, a pioneer of anti-bullying research in Norway, emphasizes the importance of creating a school environment characterized by warmth, positive interest, and involvement from adults (Olweus, 1996). He indicates that the overall value system of the school needs to incorporate caring, respect, and responsibility. The interesting outcome of Olweus' program is that not only does it see a 50 percent reduction in bullying behavior, but there is also a noted reduction in other anti-social behaviors among students, such as drinking, fighting, and vandalism. Furthermore, there is a noted increase in pro-social behaviors such as increased discipline, and a more positive attitude towards schoolwork and peer relationships (Olweus, 1996). This suggests that bullying behavior does not exist in isolation, and that there is a link between the occurrence of bullying and the general frequency of both positive and negative behaviors in the school environment.

Combating these negative behaviors, and promoting positive ones may be a more effective way to deal with bullying than measures meant to target bullies and victims directly.

Teachers can play a main role in establishing and leading this change. While research on bullying prevention has signaled the involvement of the school staff in general, incorporating teachers, principals, guidance counselors, and psychologists, there is little research exclusively examining teachers' roles. It is reasonable to think that teachers play a large role in affecting the atmosphere in a school, both because they make up a large number of the staff body and because of the close contact they have with large groups of students.

Immediate, Individualized, and Consistent Intervention Strategies

Bullying intervention, as opposed to bullying prevention, refers to the strategies and procedures that a school has in place in order to deal with a bullying incident that has already occurred. The foundation of an effective bullying intervention strategy is to provide immediate support to the victim. The literature on bullying intervention emphasizes the support of early intervention (Feinberg, 2003) and that each bullying incident should be treated with urgency and sensitivity (Oneil et al., 2012). Olweus (1994) states that providing support for victims is essential. This notion that the victim should be treated with compassion and sensitivity by the school community is one that is consistent throughout the research on bullying intervention. The goal of this immediate and sensitive response is that the victim is not made to feel as if he or she bears the responsibility to respond to the bullying incident (Oneil et al., 2012).

Literature (Feinberg, 2003) emphasized the importance of meeting the individual needs of the victim. Support for the victim necessitates that school administrators schedule follow-up meetings with victims to assess the social and emotional wellbeing of the student, as well as express the support of the school community. Maintaining open lines of communication between teachers, parents, students, and administrators is also essential (Oneil et al., 2012).

In comparison to actions taken towards the victim, there is less agreement within the literature on actions taken towards the bully. There is some, although not much, research supporting peer mediation and conflict resolution between the bully and the victim, although other research denies this approach (Oneil et al., 2012). Oneil et al. (2012) emphasize that a bullying incident is not a debate between two people of equal power and therefore should not be handled by having the two parties talk it out. Other strategies emphasize a zero tolerance approach, emphasizing that the bully has lost people's trust and will be guilty in future incidents

even if he or she is in the vicinity of another bullying event. However, this approach has been criticized for being ineffective. Joseph (2000) states that “the difficulty in laying accountability at the feet of the bully is that it pretty much guarantees that there will be repeat incidents. Bullies are in that business for the power they perceive themselves to have and the attention that is given to them.”

The research on bullying intervention is consistent that the establishment of a bullying response team, composed of different members of the staff body, is integral to effective intervention (Feinberg, 2003). Feinberg (2003) states that “the goal of bullying intervention is to create a culture in which adults stop bullying immediately.” Consistent throughout the research is the notion that increased adult supervision leads to a reduction in bullying and a more immediate response to bullying incidents (Olweus, 1994). Teachers can play a crucial role in effective bullying intervention. Teachers’ positions in the classroom make them a natural fit to be the first ones on hand to intervene in a bullying situation.

Thus, the failure of teachers to respond to a bullying situation conveys the message to students that they condone this behavior (Feinberg, 2003). She finds that between an education program aimed at the community at-large, current teachers, and preservice teachers, the one aimed at current teachers is the most effective in reducing bullying.

Another study examining prevention programs aimed at teacher education was also found to be effective, and concluded that teachers have the ability to change the social climate of a school (Bell, Raczynski, & Horne, 2010). Teachers’ roles, overall social climate, and reduction of bullying paints an optimistic picture that teachers can make a difference in bullying research.

Part of Olweus’ (1994) anti-bullying strategy is a focus on the effectiveness of non-mental health professionals in the reduction of bullying behavior. His philosophy highlights the importance of using the existing social environment of the school to protect against bullying, and indicates that teachers can act as agents of change in the social environment. O’Neil et al. (2012) further point out the need for consistency amongst the staff body of a school, both in understanding what constitutes a bullying act and in conveying to the school community at-large that the staff body has a vital interest in understanding and addressing the bullying situation. Teachers can play a vital role in both aspects.

Barriers to Effective Bullying Prevention

Barriers that do exist that prevent effective bullying programs from taking place.

However, the more information accumulated about these barriers, the sooner we can overcome them. Teachers themselves perceive a number of barriers to dealing with bullying effectively (Marshall, 2012), and this perceived helplessness can lead to a lack of action. A school’s large size can impede a staff’s belief that creating ongoing connections with students can lead to a reduction in bullying (Coyle, 2008). Another challenge to effective bullying prevention lies in the fact that much of bullying usually occurs outside the view of supervisors, which often leads to a ‘he said’, she said scenario where no definitive resolution can be reached (Joseph, 2000). However, this would indicate that Olweus’ (1994) focus on increasing adult supervision is an effective measure for reducing bullying. Lastly, there are a number of barriers that prevent effective bullying intervention from a cultural standpoint. The local community’s lack of openness to change and diversity, and intolerance to diverse groups of people are found to impede the implementation of an effective anti-bullying program (Coyle, 2008).

Themes that emerged from literature are as follows:

From the literature and theories, the following themes emerged

- Conducive school environment
- Importance and application of effective anti-bullying strategies
- The role of teachers and their theoretical knowledge base

CONCLUSION

- The impacts of bullying are widespread and can lead to serious long- and short-term problems, including physical, psychological, academic, and employment-related issues. Literature has confirmed that teachers have the ability to influence the school environment to be conducive for learning and to avoid anti-bullying theories. From the literature review it became clear that anti-bullying strategies can be taught and learnt.
- Variety of anti-bullying strategies are supposed to be used. The teacher, who looks for opportunities to use interesting words and is an active, enthusiastic word learner, can instill effective anti-bullying by implementing the strategies appropriately. School environment should be that espouses warmth, caring, and mutual respect. This can be achieved if teachers can use various strategies and understand the theories that can prevent bullying in schools.

RECOMMENDATION

Impact in the School

To impact bullying behavior, the entire school organization— students, teachers, staff, administrators, parents, and the community—must be committed to the anti-bullying mission.

This literature review analyzes multiple sources in the field of bullying prevention, some of which stem from research based articles, and others which recount first hand experiences in the classroom. The most intriguing aspect of research on bullying prevention lies not in any one solution but in the more general establishment of a school environment that espouses warmth, caring, and mutual respect. My own opinion coincides with this approach, and my hope is to focus my research on how teachers can contribute to this positive school climate.

Holt and Keyes (2004) report that “a greater proportion of studies have found that teachers report lower prevalence rates of bullying than students do” (p. 122), which likely indicates that students are aware of bullying to a much greater extent than teachers.

Efforts to help teachers increase their depth of content knowledge, as well as their pedagogical content knowledge (i.e., present content in ways that actively engage learners and promote deep understanding as opposed to rote memorization), are also important contributors to an environment that discourages bullying. However, unless teachers come to the classroom with skills that allow them to establish a culture that proactively minimizes student behavior problems and at the same time allows them to intervene in positive, educative, effective ways when students are disruptive, there is likely to be an environment that is predisposed to bullying problems.

In the light of the foregoing discussion the following recommendations are made:

- Constant monitoring of anti-bullying strategies amongst learners is imperative and clear early warning signs for bullying should be communicated to the learners.
- To address the bullying problem, various school-based bullying prevention programs and approaches have been developed, implemented, and evaluated. Support programs should be in place and constantly evaluated by experts.

Further studies have also shown that programs need to be intensive and long-lasting to reduce bullying (Ttofi & Farrington, 2011).

Chapter 131

CYBER BULLYING PARTICIPATION ROLES: EXAMINING THE RELATIONSHIP BETWEEN EMPATHY AND PSYCHOPATHY

Jessie L. Krienert*, PhD and Jeffrey A. Walsh, PhD

Criminal Justice Sciences Department, Illinois State University, Normal, IL, US

ABSTRACT

Bullying behavior, both perpetration and victimization, has generated a significant amount of attention in the wake of high profile bullying linked school shootings and youth suicides. The empirical research estimates that as many as 30-40% of youth experience bullying each year. Bullying has been linked to a host of psychosocial consequences stemming from both perpetration and victimization including: low self-esteem, depression, suicide, eating disorders, early drug and alcohol experimentation, deficits in educational achievement and motivation, relationship conflict, and aggression. While considerable knowledge has been gained about traditional bullying behavior and participation roles among the youth population (grades k-8), early adolescence (grades 9-12) and even workplace bullying, limited information exists about college students' participation in bullying behavior, specifically cyber-bullying, and the mediating/moderating influences of empathy and psychopathy. While the results have been mixed and often do not include cyber bullying, evidence supports a negative correlation between bullying and both affective and cognitive empathy. Further, though again mixed, prior research supports a relationship between bullying behavior and psychopathy with bullies scoring higher on measures of psychopathy than non-participants. The present exploratory and descriptive study utilizes a large sample of college students to examine the relationship between cyberbullying participation roles (cyberbullies, cybervictims, cyberbully-victims, and non-participant controls), empathy (cognitive and affective), and psychopathy (primary and secondary). The work also examines these relationships by gender to identify whether male and female differences exist among cyberbullies, cybervictims and cyberbully-victims across these traits.

Keywords: cyber bullying, bullying, empathy, psychopathy

INTRODUCTION

Bullying behavior in its various forms is now pervasive in society. While the behavior is not new and was once viewed as a rite-of-passage among youth (Wolke & Lereya, 2015), bullying has been reconsidered and reconceptualized in light of a growing body of new evidence and established knowledge. This reorientation has been driven by the empirically documented immediate, lingering, and long-term adverse psychosocial effects/consequences of bullying, both perpetration and victimization, over the lifecourse from childhood through adulthood and across multiple domains including: mental health, physical health, relationships, criminal involvement, victimization, and more. With links to tragic incidents of school shootings (Raitanen, Sandberg, & Oksanen, 2019) and implication tied to elevated/increasing youth suicide rates (Holt et al., 2015), combined with attention from policy makers, public officials, parents, school boards, and scholars, awareness of the consequences of bullying behavior has reached a new peak. Extant research has explored bullying behavior across many social contexts and settings including elementary school children (Hymel & Swearer, 2015), junior high school youth (Di Stasio, Savage, & Burgos, 2016), high school age adolescents (Walsh, Krienert, Thresher, & Potratz, 2018), and more recently, young adult college/university students (Gibb & Devereux, 2014). Bullying research has even extended to employees/co-workers in the workplace (Einarsen & Nielsen, 2015). Further, while traditional bullying – relational, verbal, and physical (Olweus & Limber, 2018) – remains of paramount concern garnering much of the attention and resources, attention is building for the newest subcategory of bullying – cyberbullying. Cyberbullying, the use of computers, cell phones, and other electronic devices as a medium for bullying behavior (Steffgen & König, 2009), is gaining traction, upending some of our basic understanding of bullying behavior acquired over the years, creating a new, expanded, and vastly more complex bullying paradigm. Traditional bullying research has informed a host of factors which may increase cyber bullying incidents and the myriad consequences, and although the correlates of traditional bullying may assist in understanding cyber bullying, to be certain, cyberbullying is a unique phenomenon with important distinctions from traditional forms of bullying (Bottino, Bottino, Regina, Correia, & Ribeiro, 2015; Brewer & Kerslake, 2015) requiring thorough in-depth empirical investigation, intervention, and prevention. Also, while prior literature and empirical study of bullying has frequently emphasized childhood and early adolescent bullying, college/university students have been largely neglected from much of the prior work though research finds that bullying continues into college (Adams & Lawrence, 2011). In fact, research finds evidence of continuity between the roles of bullies, victims, and bully-victims from elementary school through college (Chapell et al., 2006). Falling victim to cyberbullying in high school presents a significant risk of then being victimized in college (Kraft & Wang, 2010). Similarly, a growing body of research indicates that cyberbullying continues in college and at higher rates than previously reported (Gibb & Devereux, 2014).

Studies of traditional forms of bullying behavior have frequently found strong relationships between bullying and empathy, and bullying and psychopathy, with individuals who score lower on empathy measures, both cognitive and affective, engaging in more frequent and severe bullying (Brewer & Kerslake, 2015). Jolliffe and Farrington (2011) also found that males and females who bullied had lower scores on both cognitive and affective empathy compared to non-participants though other contradictory research has found that bullies may feel empathy

and therefore know how to more effectively manipulate, hurt, or control victims (Lamia, 2010). In essence, empathy may be a tool in the repertoire of bullying tactics. Similarly, bullying has been empirically linked to high scores on psychopathy measures with emphasis on callous-unemotional traits such as narcissism, grandiosity, lack of remorse, and impulsivity or the tendency to not consider longer-term consequences of actions. Research by Fanti and Kimonis (2013) and others has found that adolescents scoring high on narcissism, impulsivity and careless-unemotional traits were more likely to be bullies. Importantly, cyberbullying, and specifically cyberbullying among college/university students, has been under examined with regard to many of the noted correlates of traditional bullying. As Gibb and Devereux (2014) note, more research is needed to examine cyberbullying behaviors on college campuses given that few studies have done so to date. The advent of digital education has led more college campuses towards cyber communication as a means of academic and social student engagement. Similarly, college students today have grown up in the digital era that has moved communication towards electronic formats on personal devices accessing a vast landscape of social media and cyber platforms.

The present chapter expands the extant work examining the topic of cyberbullying addressing several limitations. The present study: 1) draws much needed attention and empirical investigation to the understudied, though rapidly emergent, bullying subtype of cyber bullying; 2) utilizes a large sample ($n = 1,095$) of college/university students, an under examined population in the broader bullying literature that has most frequently emphasized elementary or middle school aged youth; 3) extends cyberbullying participation categories beyond just cyberbullies and cybervictims to include the more comprehensive participation categories of cyberbully-victims and non-participants, providing more thorough context and insight with a four category cyberbullying participation typology; 4) utilizes leading psychometric instruments to assess the relationship between empathy, psychopathy, and cyberbullying participation roles to further inform the broader bullying paradigm, and finally; 5) extends prior bullying research along gender lines of inquiry examining the understudied area of male and female differences and similarities related to cyberbullying with respect to the four cyberbullying participation categories, along with empathy, and psychopathy. Greater understanding of cyberbullying and cybervictimization and associated correlates among college/university students will inform the current base of knowledge, help guide future empirical study, and enhance cyberbullying prevalence estimates, interventions, and prevention efforts.

REVIEW OF THE LITERATURE

Cyberbullying

The internet, social media platforms, changes in preferred modes of communication, and the ease of access and availability of electronic devices for social engagement have impacted our daily lives. These changes have exponentially expanded social networks, outreach, and impact in ways once unimaginable. These advances provide great societal advantage, opportunity, and positive impact as well as great social responsibility. This new digital media and technology era of email, chat, forums, blogs, social networking sites, messaging, and

numerous other applications (Pfetsch, 2017) allows for around-the-clock communication with audiences reaching far and wide. A consequence of expanded electronic communication is the opportunity for new forms of abuse and victimization. Cyberbullying, a subtype of bullying behavior (Olweus & Limber, 2018) accompanied by many of the attendant characteristics of more traditional bullying such as, intentionality, repetition, and harm to others (Patchin & Hinduja, 2015), is a rapidly growing social concern reflective of our increasing integration of technology into our daily routines. Cyberbullying has been defined as, “the intent to consistently harass another individual to cause harm via any electronic method, including social media, and includes defamation, public disclosure of private facts, and intentional emotional distress” (Watts, Wagner, Velasquez, & Behrens, 2017, p. 268). Similarly, Smith et al. (2008) define cyberbullying as aggressive, intentional acts, involving electronic forms of contact, repeated and over time against another who is unable to easily defend themselves. Studies of cyberbullying, similar to traditional bullying, have emphasized youth and adolescent populations with fewer studies undertaken at the college/university level (Watts et al., 2017).

Cyberbullying at the college level is viewed as a bridge in the continuum of bullying behavior from childhood through youth and into adulthood (Faucher, Jackson, & Cassidy, 2014). Accurate prevalence estimates of cyberbullying and victimization remains challenging due in large part to definitional inconsistencies across studies, study parameters related to the measurement and inclusion/exclusion of cyberbullying behaviors, participant reporting practices, and socially desirable responding reflective of the negative response bullying behavior has received throughout mainstream media. Estimates that exist suggest rampant involvement in cyberbullying as either a cyberbully, cybervictim, or observer/witness with rates ranging from 10-40% of youth involved in some capacity with between 8-11% percent of college students having been cyberbullied and approximately 22-50% having been victimized (See Doane, Pearson, & Kelley, 2014; Gibb & Devereux, 2014). More specific to college freshmen, Marcum, Higgins, and Ricketts (2010) found that 35.2% of male freshmen had experienced some form of cyberbullying compared to 16.0% of female freshmen (Marcum, Higgins, Freiburger, & Ricketts, 2012). At the upper-bound, Gibb and Devereux (2014) found that 51.5% of college age students engage in cyberbullying behavior. “Although prevalence rates among college students vary widely, all studies suggest that a substantial portion of college students are victims and/or perpetrators of cyberbullying” (Doane et al., 2014, p. 155). In a somewhat alarming revelation considering what is currently known about youth bullying behavior, some studies find the rates of college student participation are higher than adolescent cyberbullying participation (Kokkinos, Antoniadou, & Markos, 2014). Similarly, differences in gender based involvement in cyberbullying in college yields mixed results across studies. A review of the literature by Lund and Ross (2017) found that males perpetrate cyberbullying behavior more frequently than females with male prevalence between 10%-15% and female prevalence ranging from 3%-8% depending on study methodology. Lund and Ross (2017) also found that college student cybervictimization prevalence ranged from no differences noted between genders to studies suggesting males were victimized more frequently (15% vs 11%), and yet other studies suggesting females were victimized more frequently (10% vs. 5%)(p. 355). Gibb and Devereux (2014) in a study of 297 university students examining college cyberbullying behavior and personality found no differences between the sexes. However, males were more likely to engage in a wider range of behaviors than females suggesting there may be gender specific cyberbullying behaviors.

Cyberbullying has several notable distinctions from traditional bullying contributing to its effectiveness and impactfulness. The anonymity afforded cyberbullies provides a sense of power and control that could not be maintained through face-to-face bullying (Watts et al., 2017). Traditional bullying tends to accentuate physical stature and social status as mechanisms to embolden the bully, exert control, and render the victim powerless (Pettalia, Levin, & Dickinson, 2013). These characteristics become irrelevant to the cyberbully with the fear of reprisal significantly diminished and even unlikely when the bullying is done anonymously via the cover of technology. Similarly, the aspect of time is uniquely advantageous to the cyberbully in ways not experienced in traditional bullying incidents while at the same time being uniquely disadvantageous to the cybervictim. For example, cyberbullying can take place at any time of the day, 24 hours a day, for any duration of time. Unlike traditional bullying, cyberbullies can reach their victims long after the school day is done, class is over, or the victim has left the setting for the day. Technology allows for the posting of pictures, videos, and messages, for large audiences to see, read, hear, and share at any point in time for extended periods of time, inflicting repeated and prolonged harm on the cybervictim (Pettalia et al., 2013). The opportunity for an expanding audience of friends, acquaintances, and strangers is far beyond the reach of traditional bullying incidents. Traditional bullying tends to be much more confined in both audience exposure and incident duration. Traditional bullying is often conceptualized as repeated actions of antisocial behavior committed by the bully. Cyberbullying may occur as a singular action (ex. posting a photo, video, or negative message on social media) but with an expanding audience and no expiration date or end to the initial action. That singular act may also be conceptualized as a repeating and prolonged harm to the cybervictim.

Empathy

The extant literature defines empathy as both an affective trait facilitating the experience of the emotional state of another, as well as a cognitive ability facilitating the understanding of the emotions of another, with the intended end result being prosocial behavior inhibiting antisocial behavior (Jolliffe & Farrington, 2006, p. 540). The link between empathy, both affective and cognitive, and aggressive behavior, even bullying behavior, has been established though the results are inconclusive and often contradictory across studies. Few studies have examined the link between cyberbullying and empathy and even fewer still among a college/university population (Pfetsch, 2017). This line of inquiry, similar to traditional bullying, has resulted in inconsistent and contradictory findings across studies. For example, in a sample of 521 vocational students, Graf, Yanagida, and Spiel (2019), studying cyberbullying behavior, found as hypothesized, a negative relationship between cognitive empathy and cyberbullying. No significant relationship was identified between affective empathy and cyberbullying and they found no significant gender based differences in their models. Research by Steffgen, König, Pfetsch, and Melzer (2011), drawing on a sample of 2,070 students in grades 7-13, studying the relationship between cyberbullying and empathic response compared to traditional bullying, found that cyberbullies showed a greater lack of empathy for others being cyberbullied than did non-cyberbullies. There was no significant gender effect for

cyberbullying. Traditional bullies on the other hand, both males and females, were associated with a greater lack of empathy.

Zych, Baldry, Farrington, and Llorent (2018), in a small meta-analysis of 25 published scholarly articles examining cyberbullying and empathy, found that cyberbullying behavior was related to low empathy though cybervictimization was not. More specifically, while there was some evidence that cybervictims may have higher affective empathy, the authors conclude that more research is needed to clarify the relationship. Similarly, research by Brewer and Kerslake (2015) in a sample of 90 participants age 16-18, examining cyberbullying, self-esteem, empathy, and loneliness, found that despite noted differences between traditional and cyberbullying with regard to the context and content of bullying behavior, both traditional bullies and cyberbullies lack empathy. Further, while both cognitive and affective empathy are important to social interaction, affective empathy appears to play a particularly salient role in the development of bullying behavior. This finding needs to be further explored among college cyberbullying participation roles. The authors, due to sample size limitations, did not distinguish male and female differences in their work and instead used the aggregated sample. Alternately, research by Pfetsch (2017), studying a group of young adults between 18 and 40 years of age recruited on two campuses, found that cybervictimization was a predictor of cyberbullying behavior but that self-reported cognitive and affective empathy did not predict cyberbullying behavior. Additionally, the authors concluded that gender was not a significant predictor in the study. In the examples noted here, we identify three lines of incongruent findings symbolic of the larger body of extant literature supporting the need for additional research.

In contrast to the above empathy deficit oriented explanations, and employing a younger sample of participants, empirical work by Pettalia et al. (2013), examining 263 junior high students in grades 7 and 8 across 12 schools in Canada, found that cyberbully-victims scored significantly higher on measures of both cognitive and affective empathy than youths not involved in cyberbullying. They also found that cyberbully-victims scored higher than cyberbullies on measures of affective empathy. Similar to a small body of traditional bullying research (See Sutton, Smith, & Swettenham, 1999a, 1999b; Walsh et al., 2018), these findings suggest that cyberbully-victims are a unique group capable of understanding the perspective of others and the emotional impact of cyberbullying on others given their own cybervictimization experiences. However, cyberbully-victims are also willing to engage in the same hurtful behavior as cyberbullies (Pettalia et al., 2013). This evidence supports the social competency model suggesting that cyberbullies may be uniquely adept at understanding the emotions their victims feel and use that knowledge to their advantage. In other words, similar to some findings in the traditional bullying literature, cyberbullies may possess a strong sense of empathy or theory-of-mind that they use to their advantage to manipulate and bully most effectively (See Baughman, Dearing, Giammarco, & Vernon, 2012; Gini, 2006).

A review of the extant literature reveals that the complex link between empathy and traditional bullying is unclear and remains similarly confounding in the subtype of cyberbullying as well. There is currently no clear empirical basis established from which to draw definitive conclusions about the relationship between cyberbullying and empathy (Steffgen et al., 2011). While it is generally assumed that high levels of empathy are associated with prosocial behaviors, there is a need for additional empirical inquiry into the association between empathy and antisocial behaviors including both traditional bullying and

cyberbullying (Pettalia et al., 2013; van Noorden, Haselager, Cillessen, & Bukowski, 2014). The present chapter seeks to contribute to this important foundation in the empirical literature.

Psychopathy

Another important construct related to both antisocial behavior and empathy, and similarly understudied in both traditional and cyberbullying, is psychopathy. Psychopathy is a disorder characterized by antisocial behavior including narcissism, callousness, impulsivity, disregard for the rights of others, manipulation, lack of guilt, and participation in illegal behavior (Lockwood, 2016; Ragatz, Anderson, Fremouw, & Schwartz, 2011). Bullying among the youth population has been empirically linked to high scores on psychopathic measures with emphasis on callous-unemotional traits such as narcissism, grandiosity, lack of remorse, and impulsivity or the tendency to not consider longer-term consequences for actions. These associations have been studied much less extensively in the college/university population and among cyberbullies. Bullies have been characterized as callous towards objects of their aggression, pursuing power, control and domination over others, and participating in dangerous and risk taking behavior (van Geel, Goemans, Toprak, & Vedder, 2017). Gibb and Devereux noted in 2014, “there have been no studies to date...that directly link psychopathy to engagement in CBB [cyber bullying behavior] in either adolescent or college samples” (p.10). Fortunately, today this statement is no longer accurate though the research remains scarce and the relationship under examined.

Extant work suggests that personality traits including psychopathy predict cyberbullying behavior (Goodboy & Martin, 2015) and psychopathic attributes, in particular grandiose/manipulative behavior, has been linked to internet use (Kokkinos et al., 2014). Research by Gibb and Devereux (2014) drawing on a sample of 297 undergraduate and graduate students, found that students who scored higher on psychopathy were also more likely to report participation in cyberbullying behavior. These individuals were also more likely to occupy the dual role of victim and offender. Gender differences were not significant on measures of psychopathy. These results are similar to work with younger populations that has found traditional bullies and bully-victims score higher on measures of psychopathy than victims and controls (Ragatz et al., 2011). Kokkinos et al. (2014) in a sample of 430 college students, found that cyberbully-victims had the greatest involvement in cyberbullying and scored higher than cyberbullies, cybervictims, and uninvolved students on measures of psychopathy. Their work found notable gender differences at more finite levels of the analyses. For example, males scored higher on experience seeking, grandiose/manipulative, impulsive/irresponsible and callous/unemotional dimensions. Female participants scored higher on cognitive empathy, emotional reactivity and interpersonal sensitivity (p. 209). In sum, cyberbully-victims had significantly higher scores on all but one dimension of the psychopathy measure than the other three cyberbullying participant groups. Goodboy and Martin (2015) employed a sample of 227 undergraduate students to study visual-based and text-based cyberbullying and associations with the personality constructs present in the dark triad (Machiavellianism, psychopathy and narcissism). Their findings reveal that psychopathy was the only significant predictor in the dark triad of visual-based cyberbullying and the only significant predictor of text-based cyberbullying. The findings suggests that psychopathy is the

uniquely problematic dark triad trait. Gender differences were not included in the study and the sample was discussed in the aggregate.

The following sections of this chapter explain the methodology employed to examine the relationships between cyberbullying participation roles, empathy, and psychopathy, as well as the results of the analyses. A conclusion/discussion section is included to offer some interpretation of the results.

METHODS

Participants

Students ($N = 1,095$) from a Midwestern university were administered a confidential esurvey inquiring about their involvement in cyberbullying behavior during the past year. Replicating prior methodology utilized by Walsh et al. (2018) in their study of traditional bullying, participants were categorized into one of four participation roles: cyberbullies, cybervictims, cyberbully-victims (individuals who reported being both cyberbullies and cybervictims), or uninvolved/non-participants, based on their esurvey responses. The four cyberbullying participation categories were examined to identify differences and relationships across normed empathy and psychopathy scale scores, and by respondent sex.

Instrument

The esurvey consisted of approximately 100 multiple choice and Likert-scale type questions. The esurvey was subcategorized into four sections: 1) respondent's demographic data, 2) questions about cyberbullying adapted from Patchin and Hinduja (2015), 3) the Levenson's Self-Report Psychopathy Scale (LSRP) (primary and secondary), and 4) Jolliffe and Farrington's Basic Empathy Scale (BES) (affective and cognitive). The following section, in the interest of brevity, provides a brief description of each instrument administered in the esurvey.

CyberBullying

A scale adapted from Patchin and Hinduja (2015) was used to identify the cyberbullying participation roles of respondents. The questionnaire contained a series of Likert-scale questions assessing the frequency of cyber activities (both bullying and victimization) in the past year. Response options included: never, once or twice, 3-5 times, 6 or more times. The categorization of cyberbully, cybervictim, or cyberbully-victim relied on the lower-bound cut-point response of "1-2 times a year". Participants who responded never, were categorized as uninvolved/non-participants. Factor loadings in the present study for the cyberbullying perpetration scale ($\alpha = .783$) and the cyberbullying victimization scale ($\alpha = .785$) support their use in this research.

Empathy

Jolliffe and Farrington's Basic Empathy Scale (BES) was used to measure empathy among study participants. Items included in the BES emphasize the degree to which a person understands and shares the emotions of another (Jolliffe & Farrington, 2011). The original BES was a 40 item Likert response scale that was reduced through confirmatory factor analysis to a normed and validated 20 item scale with loadings on two factors, one factor measuring cognitive empathy and the other factor measuring affective empathy (Jolliffe & Farrington, 2006). Factor loadings in the present study for the full scale ($\alpha = .889$), cognitive empathy (9 items, $\alpha = .846$), and affective empathy (11 items, $\alpha = .859$) support their use here and well exceed minimum thresholds. Cognitive empathy is defined as the capacity of one person to comprehend and understand the emotions of another person. An example of a cognitive empathy question would be, "I often get swept up in my friend's feelings". Affective empathy is the capacity of one person to experience the emotions of another person. An example of an affective empathy question would be, "I am not usually aware of my friend's feelings". The two dimensions of empathy have support, albeit mixed, in prior bullying research though few studies have examined empathy and cyberbullying.

Psychopathy

The Levenson's Self-Report Psychopathy Scale (LSRP) was used to measure psychopathy. The LSRP consists of 26 self-report items using Likert responses on a four-point scale ranging from disagree strongly to agree strongly. Higher scores represent greater association with the psychopathy traits being measured. The LSRP consists of a total psychopathy score derived from a sum of all item responses, a primary psychopathy subscale score derived from 16 summed scale items, and a secondary psychopathy subscale score derived from summing the remaining 10 items. Factor loadings in the present study for the full 26-item LSRP scale ($\alpha = .860$), primary psychopathy (16 items, $\alpha = .863$), and secondary psychopathy (10 items, $\alpha = .705$) support their use and well exceed minimum thresholds. The primary psychopathy items assess a selfish, grandiose, callous, uncaring, and manipulative attitude or posture toward others. The secondary psychopathy items assess impulsivity, emotional reactivity, and a self-defeating lifestyle (Levenson, Kiehl, & Fitzpatrick, 1995; Lynam, Whiteside, & Jones, 1999).

ANALYSIS PLAN

The first step of the analyses involved descriptive statistics to measure the frequency and prevalence of several respondent characteristics. Descriptive statistics for the sample in its entirety and then also by cyberbullying participation categories (cyberbully, cybervictim, cyberbully-victim, non-participant) are located in Table 1. The second step of bivariate analyses, noted in Table 2, involved a series of Chi-squared tests to identify statistically significant relationships between the cyberbullying participation categories and several respondent characteristics. An ANOVA was used to identify statistically significant relationships between the four cyberbullying participation categories and the empathy and

psychopathy full scale and subscales. These results are also in Table 2. The fourth and final series of analyses, reported in Tables 4-6, include a multivariate analysis, multinomial logistic regression, to confirm aspects of the cyberbully participation relationship, empathy, psychopathy, and gender.

RESULTS/FINDINGS

The sample consisted of a majority of female students (805, 74%) compared to male students (281, 26%) and other (6, .5%) representing a higher female response rate than the actual campus population (F 58%, M 42%). As noted in Table 1, the majority of the sample was white (80%) accurately reflecting the composition of white students on campus (82%). The majority of respondents identified as heterosexual (83%) and were under 22 years of age (64%). The majority of students reported some level of participation in cyberbullying activities in the past year (62%), as cyberbullies (18%), cybervictims (15%) or cyberbully-victims (29%).

Table 2 highlights the demographic differences across cyberbullying participation categories with no significant differences identified by sex, race, or sexual orientation of the respondent. Significant differences in respondent scores on the psychopathy scale are noted. Cyberbullies and cyberbully-victims reported higher scores on the overall psychopathy scale, and on both of the subscales, primary and secondary psychopathy, with cyberbully-victims scoring the highest in all categories. The cyberbully-victim category also reveals lower cognitive empathy scores than all other participation categories. No differences were noted in affective empathy across cyberbullying participation category.

Multinomial Logistic Regression Results

The final step of the analysis includes multinomial logistic regression as a discriminant function to explain differences in cyberbullying participation over the four category typology, using students reporting no cyberbullying or cybervictimization, the nonparticipant/uninvolved group, as the reference category. Logistic regression results generally support the bivariate findings with a few notable exceptions.

Table 3 shows that cyberbullies and cyberbully-victims had significantly higher levels of psychopathy and empathy than students who were uninvolved. Results differ significantly by the gender of respondent. Males do not differ in empathy scores or psychopathy scores when compared to uninvolved respondents across all cyberbullying categories. Female’s, however, report higher levels of psychopathy across all cyberbullying categories when compared to the uninvolved group. Additionally, female cyberbullies and cyberbully-victims report higher levels of empathy than the uninvolved group, a finding contradicting much of the prior cyberbullying research though supporting cyberbullying work by Pettalia et al. (2013) and the social competency model evident in some traditional bullying research (see Walsh et al., 2018).

Table 4 examines differences in the overall sample by the psychopathy and empathy subscales in an effort to better contextualize and detail the full-scale results presented above. When examining primary and secondary psychopathy and affective and cognitive empathy subscales, cyberbullies report significantly higher levels of primary psychopathy and cognitive empathy than the uninvolved group. Cyberbully-victims report significantly higher levels of all psychopathy and empathy subscales when compared to the uninvolved group. Cybervictims report no significant differences in psychopathy or empathy when compared to the uninvolved group.

CONCLUSION

Much of the extant bullying research has emphasized traditional bullying behaviors in school based youth populations. That research has highlighted the lasting psychosocial consequences of bullying behaviors on both bullies and victims. Recent research is beginning to establish a base of knowledge supportive of bullying behavior being present across the life course extending into high school, college, and the workplace with lasting adverse consequences including anxiety, suicidality, depression, low self-esteem, and more (Copeland, Wolke, Angold, & Costello, 2013; Wolke & Lereya, 2015). While research on the continuity of bullying behavior is rather limited, research does support that college/university students engage in bullying behavior and that bullying victimization in high school increases the likelihood of victimization in college (Marcum et al., 2012; Marcum et al., 2010). Further, cyberbullying has emerged as the newest bullying threat sharing similarities with traditional bullying though containing many nuanced and overt differences making cyberbullying uniquely destructive and wholly opportunistic in this technology driven era. Chief among these differences are anonymity, audience reach, and duration of the cyberbullying event given that cyber content can remain active and visible in perpetuity. With some studies finding more than 50% of college students are involved in cyberbullying incidents (Gibb & Devereux, 2014) the present research examines the relationship between cyberbullying participation roles, empathy, and psychopathy. Empathy and psychopathy have been areas of emphasis in traditional bullying research though the results have been mixed across studies based in large part on methodological differences. Very few studies have examined these traits/constructs in relation to cyberbullying and fewer yet employing a college/university sample. The results of this exploratory, descriptive study identify differences across the four cyberbullying participation categories (cyberbullies, cybervictims, cyberbully-victims, and non-participants) and psychopathy (primary and secondary) and empathy (affective and cognitive), and by gender.

Initial review of the sample demographics shows no significant differences by gender, age, race, or sexual orientation across the four cyberbullying participation categories aligning with other research finding similar results. Results here do not comport with work that has found greater male participation in cyberbullying and as cyberbully-victims. Bivariate analyses note significant differences across participation categories for the full scale measure of psychopathy

and both subscales but not empathy or the empathy subscales. However, all three groups with an active participation role in cyberbullying scored higher on empathy measures than the non-participant group with only bullies scoring lower than non-participants on the subscale of affective empathy. Significant differences in psychopathy scores find that cyberbully-victims had the highest subscale scores on both primary and secondary psychopathy followed by cyberbullies, cybervictims and then non-participants.

Turning our attention to the multivariate analyses a more detailed picture begins to emerge. We find that cyberbullies have significantly higher primary psychopathy and cognitive empathy while cyberbully-victims have higher primary and secondary psychopathy and higher cognitive and affective empathy. When examining the results by gender we find our most informative and contributory results. Contrary to some of the prior literature, male cyberbullying participation roles show no significant differences across any of the psychopathy or empathy full or subscale scores compared to non-participants. However, female bullies have significantly higher primary and secondary psychopathy scores and cognitive empathy scores. It is the female cyberbully-victims that generate the most significant findings having higher scores on both primary and secondary psychopathy and both affective and cognitive empathy. Similar to the findings of traditional bullying research, individuals sharing the dual roles of cyberbully and cybervictim have the most deleterious profile and according to the present findings females with this distinction are a unique group.

Concerning empathy, cyber bullies may be capable of understanding the perspectives and emotions of others (cognitive empathy) while cyberbully-victims may have a heightened sensitivity and ability to both experience the emotional state of others (affective empathy) and understand others emotions and perspectives (cognitive empathy). Cyberbully-victims may be operating from a social competency model similar to findings by Walsh et al. (2018) in their study of traditional bullying participation roles. Cyberbully-victims may deeply understand the emotional impact of their cyberbullying on others given their own cybervictimization experiences but may also be more willing to engage in the same hurtful behavior as bullies.

Deficits in affective and cognitive empathy have been used to explain male bullying participation in youth, though in college/adult samples women frequently have higher empathy scores and greater ability with nonverbal skills such as identifying emotions (Faucher et al., 2014). These findings support greater participation in relational aggression by females in the form of gossiping or spreading rumors, slander, friendship betrayals and distrust, group exclusion, and other manipulative behaviors that affect and disrupt relationships (Faucher et al., 2014; Selkie, Kota, & Moreno, 2016). Unlike their male counterparts who tend to bully more overtly aggressively, female bullying behavior is more covert and secretive. The anonymity of the cyber environment facilitates a relational aggression style of bullying and provides a conducive medium and outlet for female cyberbullying behavior (Faucher et al., 2014; Selkie et al., 2016).

The finding that both female cyberbullies and cyberbully-victims scored higher on primary and secondary psychopathy compared to the non-participant category is supported by traditional bullying research examining samples of youth in general. For example, van Geel et al. (2017), in a large meta-analysis found relationships between psychopathy and bullying behavior and Ragatz et al. (2011) found that bullies and bully-victims scored higher on full scale measures of psychopathy compared to non-participants.

The primary psychopathy items assess aspects of selfishness, carelessness, narcissism, grandiosity, self-centeredness, callousness, uncaring, and manipulative attitudes towards

others. Dimensions of secondary psychopathy include impulsivity, emotional reactivity, vulnerability, irresponsibility, externalizing self-worth, self-defeating attitudes, and low-self esteem (Levenson et al., 1995; Lynam et al., 1999; Ragatz et al., 2011). These core features align with the cyberbully and cyberbully-victim experience though a more detailed micro level examination is needed to untangle which features are most prominent among these two groups of females and why female differences are greater than male differences when compared to the uninvolved group. The sex difference is evident but a thorough explanation remains elusive without additional examination.

Many youth bullying intervention and prevention programs have emphasized empathy training from the deficit model suggesting empathy levels are low or wholly lacking (Van Noorden, Haselager, Cillessen, & Bukowski, 2015). The present findings, similar to Walsh et al. (2018) do not support this deficits in empathy model. Female cyberbullies and cyberbully-victims scored higher on cognitive and affective empathy than non-participants and scored higher on primary and secondary psychopathy. Intervention and prevention might include targeting domains of psychopathy including narcissism, manipulative attitudes, uncaring emotional reactivity, impulsivity, self-defeating behavior, and low self-esteem. If the thinking patterns about self and the reactive behavior in relation to others can be alerted and changed the results show that high levels of empathy exists in these individuals and this empathy may be redirected towards prosocial behavior and outcomes.

This work, while contributory to the growing body of literature has several limitations. The study relied on students from one university and may not generalize to the larger population of university students. The operational definition of cyberbullying may not capture contemporary student understanding of the behavior and or may elicit socially desirable responding due to the heightened sense of awareness to the consequences of bullying. Also, the study relies on memory recall of participants and their cyberbullying participation may have faded over time. The present work relied on standardized measures of empathy and psychopathy and may not have been well suited for this sample. Finally, the study is descriptive not explanatory and causal inferences about our female cyberbullies and cyberbully-victims are not possible nor are we able to examine micro level factors within the subscales of psychopathy and empathy beyond a degree of speculation.

Cyberbullying is the new frontier in youth bullying behavior and evidence supports that college students are active participants. Future work needs to continue to develop micro-level understanding of the nuances of the participants. Research is developing a stronger foundation in the prevalence and profiles of participants and now interest needs to expand into micro-level understanding about when and why the behavior occurs in an effort to mitigate the consequences of the actions for both the cyberbullies and the cyberbully-victims.

Chapter 132

AGGRESSION AS A DEVELOPMENTAL DISORDER: FROM BULLYING TO ADULT DELINQUENCY

Gentian Vyshka^{1,*} and Admir Sinamati²

²Institute of Legal Medicine, Tirana, Albania

ABSTRACT

Theories of human aggression to account for developmental characteristics are mainly biological. There has been an increase in scientific work related to the importance of *amygdala* and other brain regions in recalcitrant aggressive reactions. This relationship has been proven to a certain degree, because “amygdalotomy” as it is performed by neurosurgeons is still considered a form of effective treatment for “aggressive reactions.” From self-mutilation to hetero-aggression, the role of the frontal lobe has often been associated with concepts of impulse control or the lack of such. Schizoid psychopathology offers proof of the biological roots of the disorder. The role of neurotransmitters, hormones (mainly sexual) and drugs of abuse offer another enlightening perspective for the intricate issue of effective solutions for human aggression.

The phenomenology of human aggression as it is sketched for the early-starters (involved in school bullying to minor thefts) is another theme. A positive spiral through the period of early-starter development is more applicable, with aggressive acts that become more and more severe. Comparing the increasing severity of early-starter aggression will help to better explain the course of development for the recalcitrant aggressive reactions.

Keywords: Aggression, impulsivity, explosive behavior, anti-social personality, criminogenic environment, developmental theory

INTRODUCTION

Law professionals, social workers, clinicians and psychologists have continuously attempted to define *anti-social behavior* in childhood, adolescence and adulthood, albeit without reaching a commonly accepted definition of the phenomenon. Even the basic definition of *aggression* per se is confusing. Should an action be accompanied by the *intention to harm*, for such an act to be considered an aggression? In that case, an important implication would derive itself from the intentionality of the wrongdoing. On the other hand, and much more incisively, should the models of anti-social behavior be treated or sketched universally, or should such conclusions be drawn within the context of the culture and the environmental setting? It is clearly stated, that ethnic composition and cultural background play important roles in bullying behavior and in victimization (Vervoort, 2010; Spriggs, 2007).

Actually, under a legal point of view, anti-social behavior among children and adolescents is noted as “micro-criminality,” “delinquency” or merely “vandalism” (a rough term approximating the others), when anti-social behavior among adults is strictly defined as “criminal.” Those definitions suffer from inconsistencies when it comes to psychological analysis of the latter. More attention is given to the fact that the wrongdoings are noted as such, following from a police intervention, rather than attempting to define the anti-social behavior as such. It is important to consider that micro-criminality is represented as a single, solitary act, rather than a complex of intermingled behaviors. Furthermore, early anti-social or aggressive behavior cannot be underemphasized or underestimated. Some authors have found associations between behavior at the age of three years, with future convictions and criminality as an adult (Stevenson, 2001). It is important to distinguish between the *officially reported* micro-criminality of an action deemed to be illegal and *self-reported* actions that characterize the life phase of an individual from children, parents, peers, school and similar entities.

Psychological research makes a clear distinction between the so-called *externalizing* behavioral models characterized by impulsive/anti-social actions and other aggressions, and *internalizing* behaviors such as anxiety, dysphoria, social isolation, somatization and anger (Cohn, 2012; Kim, 2011). We should of course concentrate on these externalizing issues, but clearly the two problems overlap, with internalizing behaviors playing their part as well.

Another important issue is the classificatory distinction between anti-social behavior and aggression at one side with a large spectrum of the symptomatology of attention deficit and hyperactivity disorder (ADHD), where the concomitance of ADHD and anti-social behavior is extremely high. Within this frame, aggression and anti-social behavior fit along a continuum of psychopathology, starting with basic defiance and opposition toward social rules and authority (known as *oppositional-defiant disorder*); progressing to the lifelong *conduct disorder*, and upgrading (or degrading for some) to the anti-social personality. Conceptually speaking, these disorders deserve their own description, because differences do exist (Jensen, 1997). Within the exaggerated attempt and tradition of modern psychiatry to coin categories, conduct disorder and oppositional defiant disorder are grouped within the “explosive” behavioral disorders. Both types refer to disorders starting before the eighteenth year of life. Typically the phenomenology is often visible at the age of ten. Inevitably, although not always, those categories will switch to an anti-social personality disorder as soon as the person reaches adulthood. Since the description of anti-social personality disorder recently was reviewed and thus determined by legal transgressions produced by these certain individuals, the severity of

the disorder is interrelated to the frequency of such violations. Thus, it might be a product of the legality for the proposed dichotomy between childhood explosive disorders and the anti-social personality of adulthood. In fact, declining to register or legally prosecute these rule violations by individuals of minor age might be erroneously interpreted as a lower frequency of the phenomenon in that age. It is a fact, however, that some or most of the juvenile law violators abandon their specific behavioral model during adulthood, which once dominated their childhood (McCurley, 2006).

Returning to the developmental perspective of the anti-social personality and/or his-her behavior, early childhood law violations will not necessarily produce a recidivist. Authors have focused on researching the roots of deviant behaviors of psychopathology. The more callous traits of personality and externalizing psychopathologies have been largely discussed (Barry, 2000; Cohn, 2012).

Descriptive attempts to define a “delinquent” child or individual are difficult, because anti-social behavior is to a certain degree, a personally communicative way for a subject to respond to the social environment. The delinquent subject in contrast is positioned within a psychological context, often with a different familial and social background. Personality traits and the severity or character of a personality disorder are not proportionally related to the severity of the offences produced. Specific risk factors have been well identified, regarding the persistence of offences (the so-called *persisters*) and cessation of such a phenomenon (so-called *desisters* where former child delinquents have later stopped such an activity). Here again familial risk factors and the role of the peers are considered of primary importance (Remschmidt, 2010).

Early studies of juvenile delinquency have mainly been focused on frequent psychiatric co-morbidities. In fact, delinquent minors diagnosed with conduct disorder show a very high prevalence of internalizing pathologies (Ulzen, 1998). Co-existence of a psychiatric nosology with criminal behavior is derived from the fact that during some period of life, many wrongdoers have been under psychiatric treatment. Nevertheless, because many psychiatric patients do not commit crimes, and many criminals are considered mentally sane and thus competent to stand trial and accept prosecution, efforts are needed to identify the “protective factors” that separate the disorders from each other. That is, the psychiatric diagnosis must be separated from the criminal behavior. In the psychiatric literature conduct disorder and oppositional-defiant disorders are among the most frequent in child and adolescent samples. A high proportion of adolescent delinquents have been diagnosed with conduct disorder (Ollendick, 1999). Albeit diagnosing a conduct disorder or deviating behavior might seem a simple task, where over-diagnosis is the rule overtaken from laymen, we should consider that few adolescents face police and legal consequences even during a single criminal act, such as rape or murder. The act might be a severe law violation, but it might not suffice to diagnose a conduct disorder. The task of detecting behavioral deviations in an adolescent sample within detention facilities is even more difficult, because individuals under those conditions become extremely diffident and non-cooperative, regardless of assurances that they are given for a total respect of confidentiality.

METHODOLOGIES

Terminological Considerations

When prosecuting and eventually condemning someone for perpetration of a crime, law professionals request two pre-conditions before defining the presence of individual responsibility: *actus reus* (guilty act), and *mens rea* (the state of mind indicating culpability) which are necessary components for a statutory definition of a crime (Cornell University Law School, 2012). When speaking about “the deed” [*die Tat*], Johann Goethe in his famous *Faust* foreshadowed the latter very clearly with “the force” [*die Kraft*]. Yet even the force had to be preceded from “the sense” [*der Sinn*] (Goethe, 1808). Therefore, from a historical and humanistic point of view, a misdeed (deed) has to be preceded from the sense (intentionality), and meanwhile it has to be perpetrated with some consistence, or force, to deserve its name and notoriety.

If culpability and guilt are to be proven, there is a need to justify classifications, and to grant different subtypes and categories a theoretical and empirical basis, sufficient to substantiate their meaning. Under a terminological point of view, we might distinguish:

1. An inter-personal *verbal* aggression consists in menacing, teasing or mocking, and differs substantially from *physical* aggression such as beating and thus assaulting the victim. Such a difference is not only descriptive, it is developmental as well. In fact, physical aggression appears early, achieving its peak in the pre-school years of life (4th to 6th year of life), whereas acts of verbal aggression come in later years (Parke, 1983). This is not the only timing parameter of such an aggression, because such physical acts become gradually more and more serious through time, where the severity of crimes increases and the individual becomes a medical and societal concern.
2. The aggression might be direct or indirect (relational; i.e., revenging through a third person, discrediting publicly the hostile figure, excluding such a figure from social events etc.). Indirect aggression seems a particularity of female individuals. Inter-sexual differences in aggression and the ways of expressing hostility are a well-known biological phenomenon, involving almost all taxonomic species (Miczek, 2007).
3. Anti-social (aggressive) behavior might be defined as overt or disguised (clandestine); the latter includes behavioral categories such as lying, stealing, property destruction, substance abuse, cheating and arson. Problematic children generally manifest both these types, but distinction between the overt and the disguised type is an important one.
4. Aggressive behavior might be proactive (beating, menacing) or reactive (revenging). There is an abundant amount of data regarding both these subtypes that we will detail in the table below, and discuss thereafter.

Table 1. Some differences between proactive and reactive aggression

<i>Proactive and Reactive Aggression</i>		
	PROACTIVE	REACTIVE
<i>Use of violence</i>	Purposeful and clearly oriented	Toward an environmental event
<i>Acting way</i>	Calculated and manipulative	Spontaneous
<i>The crime</i>	Controlled	Uncontrolled
<i>Period of criminal activity</i>	Longer	Sudden and unexpected
<i>Correlation with organic brain damages</i>	Unknown	Prefrontal lobe cortex; amygdale
<i>Implied neurotransmitter</i>	Unknown	Serotonin

The distinction between a proactive and a reactive assault or aggressive behavior is an important one, not only regarding the environmental frame which elicits each kind of reactions, but also due to different neuroanatomical circuits that are triggered therein, implying the presence of different neurotransmission agents as well.

Authors have coined and used equivalent terms for proactive and reactive aggression. For example, predatory aggression and defensive aggression have been used almost synonymously (Peterson, 2004) with terms we used above. The same meaning should have *impulsive aggression*, which is a synonym of the reactive type of aggression, and *instrumental aggression*, namely the proactive one (Montoya, 2012).

Anthropological Approach

The anthropological research on aggression is long running and for centuries has been a favored domain of psychiatrists. Lombroso published at the end of XVIII century two major works, whose titles will clarify from the start the author's meaning. The first one, "The criminal - the inborn delinquent - the morally insane - the epileptic" details all possible crimes one might commit, and the ways that society was dealing with them during that historical epoch (Lombroso, 1887). The anthropological theories of Lombroso went far beyond with his published atlas and descriptions he made of the anthropological features and somatic parameters of criminals of certain nations (Lombroso, 1887). He studied 383 skulls of criminals of the time, making autopsies and describing pathological changes in the viscera of these individuals, including their stomachs and so on. His atlas on the "Criminal Individual" is very sophisticated for the time. It was concentrated on skulls, but very intuitively the author grasped the relation between tattoos and anti-social behavior (Lombroso, 1887). The relation between tattoos and aggression or anti-social behavior even today is at the center of debates and current research (Cardasis, 2009). Tattoos are not the only external body marking made visible and presumably related to criminality and anti-social behavior. Skinheads and the Skinhead Movement have been blamed for aggressive acts, among others, even micro-criminality (Menicocci, 2012).

What remains from anthropological theories of Lombroso and others are of course not the skull parameters, although the actual trend is reinforcing the anthropological point of view. Instead of speaking of “small” or “big” cranium, research has concentrated on more sophisticated - still anthropological - parameters, such as size of amygdala and other surrogates of brain structure or activity (Matthies, 2012). If some authors support the idea a small amygdala leads more easily to aggression, others might hold a contrary opinion; this is not the only contradiction found within specialist circles (Whittle, 2008). Researchers obviously might not converge in their conclusions, as one might logically suppose; size of pre-frontal regions and amygdala is frequently discussed, with cingulum and other limbic regions, regaining importance in the literature (Boes, 2008).

The amount of data collected and discussed in the above mentioned studies, and many others, were not dealing with samples of damaged or injured brains. That is, they focused on persons without any traumatic lesions. In fact, the study of post-traumatic personality change and aggression is another important field of research.

Developmental Theory

Developmental theories insist that age of onset for anti-social activity and the persistence of “micro-criminal” acts are important clues that determine the gravity and the persistence of the anti-social behavior, as well as the co-existence of inter-personal and social problems of the individual. A conceptual distinction has been made between lifelong anti-social behavior and anti-social behavior manifested only and exclusively during adolescence (Moffitt, 1993). Such a distinction is contrasted with other criminological views, which consider the trend for anti-social behavior as a constant independent of age.

Developmental theories suffer from the fact that studies generally are started at a late moment of someone’s life, i.e., in individuals that, having manifested their aggression and anti-social behavior, already have reached a certain age. The actual focus and the consistent bulk of studies regarding the bullying phenomenon inside schools might be a compensation of the previous lack of interest or of sensible medical and/or psychological studies, aiming at detection of potential anti-social traits in the early childhood. Bullying was initially considered a moral issue that had to be dealt with, only by schools and teachers. That was obviously not true: bullying that resulted in schools was much more than that (Leblanc, 2001). When defining bullying as *direct* (open attacks) and *indirect* (social isolation, exclusion of the victim), it might become difficult to find any substantial difference between the concept of bullying and that of aggression generally. However, power imbalance is a characteristic in the process of bullying, especially noted inside schools (Leblanc, 2001). Aggressive behavior, on the other hand, will not necessarily be denoted through the presence of power imbalance.

According to Moffitt’s findings, there should be a criminogenic environment, giving rise to a stable aggressive model of behavior, and such an environment will find its prey in an individual with “slight neuropsychological deficits.” Adolescents that demonstrate life-course-persistent anti-social behavior, live in high-risk environments. Disadvantaged families, socio-economic hardship, inconsistent parental figures and attention deficit disorder, are all considered important risk factors (Ferguson, 1996). Moffitt goes further, through describing the life-course-persistent behavior as a kind of psychopathology per se. On the other hand, the

anti-social behavior that lasts only during adolescence has as its main characteristic the lack of continuity over the life course.

Both models (life-course-persistent and adolescence-confined) are somehow related to imprudent parenthood. Adelaide Johnson coined the term “superego lacunae,” which was embedded deeply in the psychiatric and psychological research of delinquency (Meloy, 2001). Thus, the psychodynamic hypotheses of conduct disorder and childhood delinquency suggest that children unconsciously act-out their parent’s anti-social wishes (Sadock, Sadock & Kaplan, 2008, pp. 95-96). If parents are not culpable for everything, of course, according to the psychoanalytic sources, they should play an important role in the entire process.

The classification offered from Moffitt has been generally accepted, albeit other authors have modified it substantially. There exists in fact another category of delinquents, the so-called *repentant group*, composed of individuals that manifest anti-social behavior early during the developmental process (before adolescence) who withdraw from it thereafter (Loeber, 1998). Another drawback of Moffitt’s model has to do with female delinquency, because girls that show a completely distinct developmental trajectory in the criminal career mainly defined as late-onset. This might not be a female characteristic in the entire issue, because adult-late-onset delinquency has been described from several sources even for male individuals (Zara, 2009; Wiecko, 2012).

Neurobiological Proof of Assaultiveness

Post-traumatic behavioral changes have been at the focus of several studies since 1848, when the first case of post-traumatic psychopathy in the modern time was registered. Phineas Gage survived a severe head trauma with no amnesia, no decline in his intelligence, without any speech disorder nor any motor deficit (Damasio, 1994). The irrespctive, insolent and asocial behavior this famous patient showed after the head trauma surprised his contemporaries. Afterwards, the post-traumatic behavioral disorder depicted in the Gage case, became the neuropsychological model of social deviations of behavior and of the medical interventions that were justified on those bases (Macmillan, 1992, 1996). In this case the wide damage to the left and the right frontal cortex were documented, and the concept of acquired psychopathy was translated into a biological model of anti-social and/or asocial behavior. The amount of data raised the question whether violence and anti-social behavior might have a neurobiological basis. Be it so, the entire issue could be simplified in terms of neurotransmitters and imbalance of the latter. Another famous case of post-traumatic personality changes was that of the French poet Apollinaire, although in this case the temporal lobe seems to have been involved (Bogousslavsky, 2003). Apart from the poet’s case whose personality changes were of another type far different from the theme were dealing with, in general, authors converge on the frontal lobe post-lesion changes (mainly post-traumatic). Thus, if amygdala is implied in anti-social or aggressive behavior, it should or must be inborn or at least a developmental issue, which differs from the post-traumatic equivalent, when the frontal lobe becomes a central concern.

Psychobiological and neurobiological influences have been implied in aggression generation and assaultive tendencies. Although internalizing disorders such as anxiety and depression might seem quite opposite to externalizing disorders such as conduct disorder and oppositional-defiant disorder, nevertheless, it has been suggested that both these types of disorders might accompany each other (Zoccolillo, 1992). Conduct disorder and depression

have a high comorbidity. Important questions are raised (a) whether major depression might give rise to aggressive actions; (b) whether conduct disorder and the problems it creates might cause dysphoria and demoralization; (c) whether other overt or covert factors might influence the symptomatology.

A decreased serotonergic activity seems to be related with impulsivity and aggression, as well as suicidal tendencies. It was Raleigh (1991) who studied initially the role of serotonergic medication on aggressive behavior, through agonists of serotonin [*tryptophan*, *fluoxetine*] or antagonists of this neurotransmitter [*cyproheptadine*]. From the neurobiological point of view, auto-aggression and hetero-aggression (respectively translated into suicide and attempted homicide) are related to a low concentration of brain serotonin. Serotonin is a neurotransmitter whose main synthesis is embedded in the brainstem. Nevertheless, axonal structures originating therein reach the forebrain structures (i.e., frontal lobes and orbitofrontal cortex), among others.

Amygdala, an almond-shaped nucleus located bilaterally in the temporal lobes, as mentioned above, has as well been at the center of different studies. Its role in the emotional and vegetative life, as a substantial part of the limbic cortex, has been studied since Klüver-Bucy syndrome was first described in humans, after initial symptomatology was detected in monkeys (Lilly, 1983). This syndrome is an expression of hyper-orality and hyper-sexuality; yet lesions of temporal lobes were initially found to have a taming effect in animals. Goltz, a famous German physiologist of the 19th century, published several papers on localization values of different lesions inside the brain (Pauly, 2005).

Surgical removal of both amygdalae was experimented in high primates more than half a century before (Morgane, 1957; Schwartzbaum, 1960). The behavioral changes following bilateral destruction of these nuclei led to the idea that amygdectomy might be a solution for refractory aggressive behavior. Although the procedure has serious ethical implications and its application in human patients is very restricted, some neurosurgeons still perform it, using the alternative form of amygdalotomy, through stereotaxic approaches (Fountas, 2007).

It is worth mentioning that neurobiological theories of aggressive behavior are not restricted to cortical or sub-cortical territories. Of course, hormonal changes registered when testosterone or cortisol are implicated, might quite well not be peripheral-originated, but rather a disturbance of the hypothalamic-hypophyseal axis, translated in the form of disequilibrium in the target endocrine gland, be it the testicle or adrenal gland. Thus, pharmacological or surgical castration has been found effective in decreasing aggressive behaviors in different mammals. Low cortisol levels have as well been related with persistent anti-social and disruptive behavior (McBurnett, 1999). Cortisol and testosterone, both playing a part in the complicated human aggression behavioral mechanisms, seem also to be interrelated, with the basal levels of the second hormone predicting the changes noted in the hypothalamic (Mehta, 2008).

Forensic Approach

Post-traumatic or not, the fact is that behavioral traits of criminals have been studied extensively during the last decades. Technology has improved through modern imaging methods. Authors have scanned convicted criminals, trying to deepen our knowledge of human aggression, particularly the anti-social behavior and misdeeds that have been perpetrated by criminals. The question has become more complex. Remote studies were focused originally on

anatomical changes, being gradually being replaced by functional studies. New horizons have been explored toward explaining functional brain changes through mostly positron emission tomography (PET) and magnetic resonance imaging (MRI). These explorations have been with the brains of both “notorious” and “common” delinquents. Hypofrontality has been the mainstream focus of research models and hypotheses.

Deterioration in the controlling functions of the prefrontal lobe is not necessarily post-traumatic, but, nonetheless, the brain is best observed when trauma is present and anatomically observable. External signs of trauma provide the best verification of hypofrontality through the assessment of glucose metabolism using PET. In a study conducted by Raine (1994), twenty-two murderers had significantly lower glucose metabolism in the prefrontal cortex, when compared to controls. The author later hypothesized that excessive sub-cortical activity predisposes aggression, thus indicating insufficient prefrontal control of this subcortical excess, but only in impulsive perpetrators (Raine, 1998). Both studies by Raine (1998, 1994) were based on glucose metabolism as detected from positron emission tomography. The first objective proof of difference between an impulsive criminal, who acts in the moment, and a predatory perpetrator, whose crime is carefully planned, was offered in these two studies. A planned, “proactive” or “predatory” crime is perpetrated by a person whose forebrain shows no significant differences in metabolizing glucose from normal controls (see Raine, 1998).

Vignettes

1st case - At the end of 2010 the Albanian public was shocked by the case of a thirteen-year-old boy, arrested and charged with two killings. Both victims were females aged 40-50 years old, who were acquaintances of the young delinquent. Each woman was raped post-mortem. The police succeeded in arresting the boy as both crimes were non-professionally perpetrated and the respective crime scenes were full of clues. Nevertheless, it is worth mentioning that the second crime was perpetrated four months after the first. This time lapse was unexplained by the police, which meant the perpetrator was still at large. Treating a minor who was, beyond all doubts, guilty for the first, initially unresolved crime was eventually was perceived as a major investigative error.

A judicial controversy was raised immediately upon pre-detention, before the thirteen-year-old minor confessed to both crimes. The Albanian criminal code requires a minimum age of 14 years as a necessary age for a person to stand trial or, as occurred in this case, to be charged with a crime. In an obvious judicial impasse, the Court of Appeal in a Southern Albanian district freed the boy two months after his arrest, as the individual could not be prosecuted and stand trial, as he was a minor.

Meanwhile, a psychiatric forensic examination was performed during pre-detention by a team of infantile psychiatrists and psychologists. No obvious psychiatric diagnosis was available, but the psychological interview revealed several drawbacks in his childhood. Growing up in a separate family (although not divorced, the father had immigrated several years earlier in order to support the family), the boy’s explosive behavior was admitted by the mother. The boy himself confessed to several previous and unreported acts of intra-familial violence. In one instance, he seriously beat his younger sister. Each incident was followed by a runaway period, when he would leave the family for two to eight days, during which time he committed small vagabond misdeeds in the suburban areas of his native city.

The boy was considered legally non-competent and his father was assigned the responsibility for his care. Immediately thereafter, however, the father again left the country, this time immigrating together with his son. No further acts of delinquency have been reported, although the two men actually live outside Albanian judiciary jurisdiction.

2nd case - A 43-year-old individual murdered a person after a car collision, during a futile quarrel and discussion that followed the accident. The person who committed the homicide was immediately arrested through a massive police operation in 2008. This individual was notorious for his impulsive acts and previous penal record, although none of his prior misdeeds was so severe. A psychiatric examination was immediately commissioned, owing to obvious signs of an anamnestic cranial trauma, and the fact that he was continuously under anti-epileptic treatment for refractory seizures. At the time he was taking Carbamazepine in therapeutic dosages.

The post-traumatic epilepsy and frontal trauma were incontestable. The plasma drug levels of Carbamazepine were within therapeutic range. The cranial trauma that the accused had suffered was caused by a bullet, which apparently was accidental, ten years before the more recent murder that he perpetrated. The Figure 1 illustrates the sequelae of the bullet and cicatrix (“scar”) in the prefrontal right region of the individual.

An insanity defense was raised by the family attorney, but not successfully upheld in the Court of Appeal. The hypofrontality was considered a mitigating factor. The accused’s inability to control impulses was classified as an insufficient presence of the *actus reus*. Because his aggression was reactive and uncontrolled, he was obviously unable to stop impulsivity. Since the other major factor, namely *mens rea*, was still present (he was considered able to produce intentionally criminal acts), and a successful insanity defense as a rule requires the loss of both elements (simultaneous insufficiency of the *actus reus* and the *mens rea*), he was found guilty with a mitigating sentence.

Forensic casuistics suggest that a syndrome provoked from lesions to the orbitofrontal cortex, where symptomatology is directly related to the “hypofrontality,” will mirror its severity through sudden and unexpected explosive behavior, lack of emotional sensitivity, asocial and inadequate manners and labile affect (Grimes, 2000). The case that we described above, with obvious signs of prefrontal lesions, illustrates the major role the frontal lobe has in the generation of impulsivity and its control.

Figure 1. Wide right prefrontal cicatrix, caused from a bullet shot wound.

Pharmacological Approach

In an attempt to simplify the phenomenology of human aggression, treatment options offer an almost independent perspective of the entire criminological diagnostic field. The revised *Psychopathy-Checklist* (PCL-R) comprises a list of symptoms, but importantly, pharmacological options are offered and suggested, based on symptomatology (Hare, 1991). This symptom-oriented treatment focuses mainly on impulsivity and aggressive behavior. “Treatable” symptoms correspond to the so-called factor 2 of PCL-R (anti-social and impulsive life style). Thus, elements related to factor 2 in the frame of the so-called “psychopathy” are more compliant to treatment, in contrast to elements of the so-called Factor 1, such as interpersonal deficits that mainly include a lack of empathy, irresponsibility, among others. In fact, pharmacological interventions are much more effective toward “positive” or “productive” symptomatology, rather than improving social inadequacies of the aggressive individual.

Anecdotal treatments are widely suggested, but multi-centric, double-blind studies are scarce or non-existent. In fact, applying certain treatments to a precise target group, such as violent prisoners, involves major ethical and legal controversies in many countries, including Albania. Therefore it seems logical that the pharmacology of anti-social behavior and of the aggression (be it sexual or not), is far from being codified.

1. Serotonin and SSRI are the first pharmacological class that has been studied and applied. Since aggression and impulsivity are due to serotonin depletion inside the central nervous system, the inhibitors of its re-uptake have been tested in ability to control symptoms. It is suggested that SSRI drugs reduce irritability, impulsivity and anti-social behavior. These drugs might even normalize the perception of expressed fear in human faces (Harmer, 2003). In fact, fear perception is considered lacking in brutal perpetrators.
2. Lithium, anti-epileptics and mood stabilizers are some other pharmacological classes of agents that have been studied purposefully. Anti-epileptics (phenytoin) have been suggested to control aggressive behavior even among non-epileptic prisoners (Barratt, 1991). Levetiracetam and oxcarbazepine are other recently applied drugs in two successive studies from the anti-epileptic class (Mattes, 2012). It is worth mentioning that in all reports, the efficacy of the antiepileptics has been considered as limited, and studies have suffered serious biases.
3. If serotonin depletion is correlated to aggression, it seems that with dopamine we have the opposite balance. An increased dopaminergic activity is found in the frame of aggressive and impulsive behavioral models, where an individual searches pathologically for pleasure or inappropriate sensation-seeking. Newer anti-psychotics, such as clozapine, manifest their anti-aggressive effect, and it seems they do so, separately from their influencing on other positive psychotic symptoms (Citrome, 2001).
4. Benzodiazepines have been suggested as effective drugs for “smoothing” impulsivity, but due to their potential for creating dependence, their use is restricted to psychiatric emergencies. Much more important, several authors suggest that some criminals abuse benzodiazepines, just to “calm down” before perpetrating a crime (Dåderman, 2010).
5. Beta-blockers have been suggested as a second-line treatment in the case of agitation or aggression, following head injury (Fleminger, 2003).

6. Sexual hormones have been continuously scrutinized, especially testosterone, whose plasmatic levels correlate fairly well with violent and aggressive behavior, extraversion, sensation-seeking, delinquent recidivism and above all, with sexual violence. Appropriate medications that lower the plasmatic level of testosterone are available [TLM or testosterone-lowering medications], and their role has been reviewed (Turner, 2012). It seems that testosterone influences mainly the aggressive impetus; whereas serotonin (see point 1) has a primary role in aggravating impulsivity. The sexual hormone hypothesis has progressed to where some authors have documented the modulating or smoothing effects of estradiol (female hormone) for the negative inter-personal effects provoked from male alcoholism (Eriksson, 2003).
7. Low plasmatic levels of cholesterol have been found to be responsible for non-natural deaths, i.e., suicides, violent deaths and accidents. It might be possible that abnormally lower plasmatic cholesterol levels unfold through an endogenous serotonin insufficiency. Within this frame, a double-blind study offering alimentary supplements composed of fatty acids (omega-6 and omega-3) to a group of violent prisoners, Gersch (2002) observed a consistent decrease of assaults and violence within the detention facility. Very important, however, is the conclusion of Gersch that dietary interventions should be considered when addressing anti-social behaviors.

CONCLUSION

There must be a continuum in the temporal behavior of individuals starting from early infancy that leaves traces, even into adulthood. Nevertheless, models are not universally accepted and cases are shaped individually. Far from having a uniform effect, we are dealing with a panoply of developmental and eventually, criminological pathways that will not necessarily lead to a common final destination.

Aggressive behavior expressed during infancy and early childhood is not intrinsically pathological, as long as these behavioral models serve an evolving life, and the surrounding environment generates no problems manifested during these formative periods. Early expressions of aggression will help the child to confirm himself/herself to personal will and desires, thus permitting the child to shape an ego and, thereafter, to understand the responsibilities and limitations of a social life. If minor violence is unimportant and futile during the age span from one to four years of life, and considered as normal, especially in response to frustration, another issue is how to deal with this problem outside a family setting, mainly in schools, where teachers “stand-in” for parents and consistent discomfort might be created. A vicious circle of aggression will be formed once the home-based parental figure responds to any aggressive behavior performed by the infant or toddler with the same way of acting-out, whereby the child psyche will internalize a high level of anxiety.

The persistence of violent acts beyond the fourth year of age might be considered as equivalent to insufficiencies in affective investment, mainly from the mother toward her progeny, once other organic causes have been carefully ruled out for children with sensorial deficiencies, such as deafness, mental retardation, etc. These pathologies might easily provoke aggressive and explosive behaviors from the handicapped child.

When dealing with an oppositional-defiant disorder, medical professionals should consider that passive oppositional behavior, when persistent, frequently is a disguise for latent depression, and depressions usually are under-treated in childhood (Keller, 1991).

Other situations worth mentioning include parental and societal distress related to runaway kids and thieving, as both these phenomena have a developmental trajectory. Behaviors such as these finish almost inevitably by becoming a law enforcement issue with potential detainment and imprisonment for the adolescent. Familial dismemberment is an important etiological factor, and children living with a divorced parent frequently run away from home. Stealing in contrast is an act that often begins in the home. A very interesting issue is the continuity and chronology of acts of theft: initially the child steals within the family. Thereafter, the act is repeated outside the family, possibly with an accomplice acquaintance of the small (child) burglar. Quite often alimentary objects are among the first to get robbed. Later the child steals money or other symbolic objects which for him are very important; for young boys, for example, stealing female lingerie takes on special meaning. Stealing and thieving have their sub-categories. Some children might show high levels of anxiety and experience a sense of guilt following the misdeed. One important consideration is the observation that some children almost purposefully act through misdeeds with the aim of or need for their stealing to be uncovered. This is the so-called "self-punishing theft" postulated by Alexander and Staub (1929). These authors write "[...] exactly the theft of desserts will serve, to provoke the punishment" [*Eine Erinnerung seiner früheren Jugend gibt uns darüber Aufschluß, warum er gerade den Diebstahl von Süßigkeiten dazu benutzt, die Strafe zu provozieren*] (p. 92).

Concluding this wide argument for the roots of human aggression, we need to again raise the question, whether we are dealing with a mental disorder or the psychopathology of a criminal. Wakefield (1992) proposed a group of dual criteria in order to characterize mental disorders as such. First, a deviant behavior or an aberrant emotional model should create consistent harm and/or suffering to the individual and his/her environment. Second, the behavioral model has to be dysfunctional, a definition which aims to bypass the cultural uniqueness of some deviations. In defining this concept, Wakefield positioned an active dysfunction under an evolutionary point of view, wherein harming another human was viewed as a behavior that was inappropriate within civil society.

Current perspectives, however, are converging more and more to interrelationships among several risk factors that might lead to delinquency and thus enable practitioners to forecast anti-social activity in the years to come over an individual's lifetime. Children with ADHD (attention-deficit, hyperactivity disorder), and those with aggressive behavior and callous personality traits, will obviously be at high risk for manifesting overt psychopathology during adulthood. There is an ontological and evolutionary trend in the delinquent activity and wrongdoings of children of today and even for future adults. Solutions need to consider this continuum of lifetime phases, before acting at a single moment in time, thus restricting in an unfortunate and substantial way the success of an intervention designed for both immediate remedy and a lifetime of good health and social responsibility.

Chapter 133

PEER ASSAULT: PROBLEMS ASSOCIATED WITH BULLYING

***Caleb McCoy, Brian Johnson, Yinan Zhao, Emily Salyer

Department of Psychology, Mississippi State University, Mississippi State, MS USA

ABSTRACT

Bullying is a risk factor that can impede children's physical and psychological health. The act of bullying is often described as physically aggressive behaviors and/or verbal aggression toward someone who is portrayed as socially and emotionally weak and/or defenseless. The occurrence of bullying might seem to take place without specific reasons. Verbal bullying is expressed through insults and/or aggressive language to harm the victim, whereas physical bullying involves actual bodily harm through aggressive acts. Bullying happens within various settings including families, educational settings, work places, and over the Internet and other electronic media (i.e., cyber bullying). Specific types of bullying across various settings are discussed within the context of prevention efforts to reduce their occurrence as well as their negative psychological impacts. Overall, bullying is associated with both short-term and long-term negative effects that impact the development of children, adolescents and adults. These effects range from having low self-esteem to the possibility of suicide. However, the presence of programs in schools and involvement of the parents in the educational system can help to reduce bullying and its associated consequences.

Keywords: Bullying, psychological effects, prevention, school/family/ workplace, cyber-bullying

INTRODUCTION

Although public awareness seems to have increased in recent years, bullying has been a common phenomenon among children and teenagers for a long period of time. Based on a study in the United States, 17% of children from grades six to ten have experienced an act of being bullied, and 19% of them are reported to be “bullies” (Jimerson, Swearer & Espelage, 2010). This high percentage of bullying in the United States has already drawn considerable attention, as it relates to children’s development. Bullying can produce seriously negative effects on children’s physical and psychological health.

Bullying is an omnipresent phenomenon. However, it is predominantly witnessed in the halls of the educational systems. Bullying is a devastating occurrence that all people have either seen or themselves been a victim. *Bullying* can be defined as any form of aggressive behavior distinguished by repeated exposure over time, which results in injury and/or discomfort against vulnerable victims who cannot easily defend themselves against one or more other people (Ahmed, Braithwaite, 2006; Richard, Schneider & Mallet, 2011). Exposure to bullying is common in countries worldwide. Bullying can take place in multiple places, which usually include but are not limited to, educational systems and work places, online social networks, and through “texting” by means of cell phones. It takes place among siblings and family members, friends and acquaintances, and co-workers and classmates. These behaviors involve intentionally harmful, physical and social aggression in a milieu of authority or power imbalance between the bully and his/her victim. Bullying can be overt, which involves the action of a direct physical or verbal attack, but it can also be covert, which involves the perpetrator(s) secretly encouraging other children to “pick on” or “to ignore” a specific person or classmate. The act of bullying can involve as few as two people, where this relationship is labeled *bully versus victim engagement*. Bystanders to the bullying act are those who witness the act and do nothing about it. Thus, they are indirectly involved. Bullying aggression also can involve a group of people where there may be multiple bullies, victims and bystanders. In some prevention programs, the “bystander” is the key link in teaching young people the foundations of managing bullying.

It is estimated that one in five school children experience the effects of bullying (Ttofi & Farrington, 2008). Of these children, four sub-types of students may be directly or indirectly involved. The “bully” is easily recognized as the person who directly causes the harm against another person(s). The “bullied” is directly harmed by the bully. These roles are not absolute. Specifically, some children can take on both roles in what is termed as the “bully-victim,” defined as someone who has been bullied themselves and who becomes a “bully” by projecting their past involvement as the “bullied” onto others. The fourth and final sub-type is the individual who is classified as “uninvolved.” They tend to be bystanders who witness the bullying but choose to do nothing about it and often have the idea that someone else knows how to better handle the situation (Goldweber, Waasdorp & Bradshaw, 2012).

WHO IS THE BULLY?

Traditional views of bullies have stereotyped them as having low self-esteem and taking out their insecurities on victims. Recent findings have shown this to not be the case. Instead,

research has shown that bullies tend to have high but unstable self-esteem, high aggression, and low social competency (Matthiesen & Einarsen, 2007). It also has been found that children who are victims of bullying or child abuse are much more likely to become adult bullies (Harvey et al, 2006).

Boys typically use the overt type of engagement to directly confront, harass, taunt and belittle peers and others, both physically and emotionally, in order to express and protect their power or authority in the social environment where they are present (Hutzell & Payne, 2012). Boys who express social dominance and persuasiveness in this fashion typically have had a prior experience of being victims themselves and are usually able to get peer support for this behavior. Across their educational experience from pre-school to college, continuation of these roles occurs. Males are more commonly the perpetrator of overt bullying in elementary, high school and college. However, girls are typically the victim and perpetrator of covert bullying from pre-school to college with a peak in middle school (Chapell et al, 2006). Females characteristically gossip, start rumors, turn friends against each other, and ostracize others to avoid and conceal direct confrontation, but they are not at all exempt from using external aggression. Both males and females use aggression in various forms to gain and hold power in social networks and to cover insecurities that they may have, which commonly develop from being bullied in the past (Farmer, Farmer, Estell & Hutchins, 2007). The progression of these relationships continues through educational settings. Typically the roles do not change from high school to college. After establishing their role as a bully or victim, little change occurs due to the social harm and deprivation that has occurred. These roles often are reinforced by attracting attention; encouragement often comes from bystanders who are peers (Richard et al, 2011). Although their trajectory of involvement is longer, girls at times are more likely to aid those who are being bullied, unlike their male counterparts.

The role of a bully is not limited to just students. These actions also can be performed by administrative positions in schools as well. Although bullying by administrators can happen throughout the school years, this role is more common among college instructors and coaches. Bullies who are peers often use physical confrontations, whereas this type of action is highly unlikely among coaches and even rarer among instructors. Those who are in a position of authority often use ways that cannot be traced by those of higher authority but it can be witnessed by other students (Chapell et al, 2006).

WHO IS BEING BULLIED?

In many cases, it is easy to mistake bullying as teasing. Thus, a lot of bullying behaviors are treated as mild teasing by teachers and parents. Teasing happens very frequently among children and does not produce the severe effects associated with bullying. Instead of serious aggressive behaviors, teasing usually includes playful name-calling and put-downs without aggression. Further, teasing usually happens once rather than in a repetitive pattern, which is characteristic of bullying (Drew, 2010). The purpose of teasing is to make jokes rather than intentional harming. On the contrary, bullying is more than making jokes on others; it is a repetitive pattern of intentionally harming others that can include anti-social behaviors. Sometimes when children complain about being bullied by peers in school, parents may just treat it as teasing among children. Under such circumstances, parents and teachers might be ignoring bullying behavior. When parents and teachers cannot clearly identify between the two,

children who are experiencing bullying might not receive immediate help. Over the long-term, their development may be seriously threatened.

Few studies have been done on the reasons why specific students are targeted and victimized by bullying. Some have shown mixed correlations between race of victim and offender. These correlations have shown that in some areas of society, African Americans are less likely to be bullied than Caucasian and Hispanic youth, but in other areas frequented by same-race peers, they are at higher risk. In regards to a general rate of bullying, statistics have shown that African American youth are more likely to participate and be labeled by teachers and peers in the bullying sub-group as a perpetrator and less likely as the victim. In regard to associations of bullying with race, the context and environment must be taken into consideration when trying to examine predictors of bullying.

Urban areas tend to be viewed with a more negative image of their social environment with the assumption of increasing victimization rates of bullying toward African Americans than in non-urban areas. In fact, ‘urbanicity’ has a direct effect on who is bullied. Little differences are found in bullying toward specific races, when household income is controlled. In these cases, when household income is comparable between groups, both Caucasians and African Americans have equal risks of being victimized by bullies. This victimization comes from direct discrimination based on gender, race, religion, sexuality or socio-economic status. Other studies have shown that a student’s physical representation, such as the way of talking, the way that one dresses and “the look” one chooses to portray are among the highest predictors to whether they are bullied or not (Goldweber, Waasdorp & Bradshaw, 2012).

Sexuality also plays an enormous role in who is victimized by bullies. Those who do not conform to the social norms of heterosexuality and gender roles are at high risks of being bullied (Toomey, Ryan, Diaz, Card & Russell, 2010). Males who tend to be effeminate and females who are perceived as being masculine tend to be targeted by bullies, regardless of their actual sexual orientation. Refusal to comply with these societal norms and/or openly expressing their sexuality often leads to negative responses from peer groups including physical assault, social ostracizing and verbal aggressions (Toomey et al, 2010).

Overall, victims of bullying are often those perceived as weaker or in some way different from other students. Those who are given a stereotypical name such as “nerd” or “geek” are typically more likely to be victimized across educational settings. Because of labels, some students are unable to acquire social prominence within the school and often are not able to gain the social support that other students have. Students labeled as popular are generally unlikely to be victimized and are more likely to be the bully. Although some youth labeled as a bully may not be popular, they seek to gain a dominant position over other students. Research has shown that those who use aggression to declare their power in the school system often use manipulation to control their peers and social world (Farmer et al, 2012). Those who use this technique are often using aggression and manipulation to fulfill their own needs and insecurities.

AUTHORITATIVE ROLES AND THE SCHOOL ENVIRONMENT

The social progression of bullying is not limited to the influence of other students but also includes the influence of parents and other authority figures. These adults (e.g., teachers,

coaches, parents) can either increase or decrease the negative effects of bullying by either acknowledging the problem and intervening or over-looking the incident and choosing to ignore the situation. In actuality, bullying is a group effort and is never the fault of one child (Richard et al, 2011). The influence that parents, teachers and coaches play has a direct role in whether a student becomes a bully or not. A child who does not receive the proper attention to become socially and emotionally adept as a student often lashes out and projects anger onto other students. By making the classroom a positive environment for all students, where the teacher believes in each student's potential and gives them a sense of appreciation, bullying is likely to decrease among students (Richard et al, 2011). The goal in each school is to sustain a bully-free environment and make the learning environment a positive place to be educated and learn key social abilities that each student will be able to use as they progress into later adolescence and adulthood.

Teachers' roles are more important than any bully prevention policy that schools can offer (Richard et al, 2011). By creating a positive learning environment and by making the material interesting, both teachers and students experience less stress, which results in decreased bullying. Thus, school policies are important and must be clarified to sustain a well-structured educational environment. This social structure and the academic program the school offers are thought to be linked with the severity of bullying in the educational system (Richard et al, 2011). Students with low interest in school are more likely to display aggressive behaviors in school, unlike schools with committed teachers and school administration. Bullying within the school system is amplified with today's technology. Because of the increased usage of cell phones and online social media networks, bullying takes place in more environments than ever before.

CYBER BULLYING

The past few decades have seen huge technological shifts, including computers, the internet and cell phones. These advances have vastly altered the way that we communicate. Some of these new modes of communication include interactive possibilities such as texting, blogs and social media. One study reported that 93% of teens actively use the internet and 75% have a cell phone (Schneider, O'Donnell, Stueve & Coulter, 2012). These new platforms for communication and connectivity have created a new delivery method for bullying. This new form of bullying is called *cyber bullying*, which can be defined as the use of e-mails, cell phones, instant messenger, chat rooms, and/or social networking websites to scare, harass or intimidate someone. This can include directly harassing or targeting by using social media to exclude or torment, including the misuse of pictures or video (Menesini & Nocentini, 2009).

Prevalence rates for cyber bullying vary depending on the method and the definition that the researchers used to identify what constitutes cyber bullying. Studies shows anywhere between four to 36 percent of people have experienced cyber bullying (Barlett & Gentile, 2012). The two main electronic devices through which cyber bullying can occur are computers and cell phones (Privitera & Campbell, 2009). These devices allow for remoteness and anonymity, the two things that researchers believe may make cyber bullying an easier mode of bullying than traditional ways (Dooley, Pyżalski & Cross, 2009). Remoteness allows the bully not to have to see the pain which he/she has inflicted because it avoids face-to-face

confrontation. Anonymity and remoteness also give bullies a better chance at avoiding conflict and/or negative consequence that might arise. Many believe that they can avoid getting into trouble from this form of bullying because they believe that what they say online will not be found or taken the wrong way, and if it is, they can say that they were “just joking” (Barlett & Gentile, 2012).

When it comes to cyber bullying, many underlying factors play a role in who is victimized. Smith and associates (2008) suggest that evidence as to which sex is more likely to be the transgressor of cyber bullying is mixed. Most studies suggest that males and females are equally likely to be a cyber-bully, whereas a few suggest that one sex is more likely to be a cyber-bully than the other. When asked who students thought would be more likely to use technology to bully, students were more likely to report that females were. They stated that because females use social technology more they are more prone to certain forms of social bullying, so they would be more likely to be a cyber-bully. Students further stated that males are more likely to be physical, and they believed their bullying would not go beyond that. Despite these perceptions, no significant gender differences between girls and boys have been found (Smith et al, 2008).

Research has indicated a crossover between traditional bullying and cyber bullying. Those who are bullies in a traditional sense are more likely to be cyber bullies. The same is true for the victims of traditional bullying. They also are more likely to be the victim of cyber bullies. A power imbalance is still present when cyber bullying occurs. In both forms of bullying a powerful perpetrator bullies a weaker victim. However, the anonymity offered by technology erases typical physical or social power imbalances and creates a new power imbalance (Barlett & Gentile, 2012; Dooley et al, 2009).

Cyber bullying, like traditional bullying, is not limited to childhood and adolescence. Technological advances in the workplace have allowed cyber bullying to follow the same trend. Depending on the strictness of the definition, the prevalence of cyber bullying in the work place ranges from 11 to over 50 percent. A notable difference between cyber bullying at work and during childhood and adolescence is that cyber bullying at work is more likely to be accompanied by traditional bullying practices, whereas children and adolescents often report that they have only experienced cyber bullying (Privitera & Campbell, 2009).

Like traditional bullying, cyber bullying can lead to increased psychological distress such as depression, anxiety, and suicide for those who are victimized. One study of Pacific Islander high school students reported the incidence of binge drinking tripled for those who had been victims of cyber bullying (Goebert, Else, Matsu, Chung-Do & Chang, 2011). Reports in another study indicate that those who were only cyber bullied experienced more distress than those who are only bullied in the more traditional social form (Schneider et al, 2012). Finally, another study asked students to indicate which style of bullying they felt was more harmful. Most forms were rated as equally harmful, but picture/video bullying was rated as the worst. Many students commented on the added anxiety of not knowing who you are facing could sometimes make cyber bullying more frightening (Smith et al, 2008).

Cyber bullying is a relatively new phenomenon and researchers agree that it has yet to be addressed in an appropriate manner. When asked about how they feel it should be handled, students responded that it was something that could be stopped without ridding the world of these means of technological communication. However, they did suggest that victims tell someone and that campaigns be aimed to alert the bully of the consequences of his or her actions (Smith et al, 2008). Most states now mandate that schools address the issue of cyber bullying,

although little consistency exists in how much emphasis schools place on it. Schools can only do so much because the acts of cyber bullying mostly occur outside of schools (Schneider et al, 2012) even if results appear during school hours when social media is accessed. Prevention and early intervention are the best ways to curtail such activities. It is important for parents and teachers to be aware of the signs of cyber bullying and to keep open the channels of communication. Several websites are available, such as www.stopcyberbullying.org and www.cyberbullyhelp.com that can serve as a good first step in addressing the issue of cyber bullying (Goebert et al, 2011).

SIBLING BULLYING

School bullying is the type that is most commonly reported. It has become a serious public concern. Research on sibling bullying or bullying at home seems scant. The lack of reports of family bullying does not mean that it produces less harmful effects. In reality, similar to the effects of school bullying, family bullying can bring lifetime negative consequence for the victims.

Bullying among siblings is one of the most common types of bullying. It can be recognized when one child in the family constantly produces insulting words or aggressive behaviors towards siblings. A variety of factors are associated with bullying among siblings. Birth order is one of the most important contributors. The first-born child or the older child is usually physically stronger than the younger one, and the physical advantages may be the prerequisite to produce aggressive behaviors towards younger siblings (Menesini, 2010). In addition, the first-born child may be the focus of the family and is likely to obtain special care and attention from parents before the siblings are born (Menesini, 2010). It is easy for older children to apply authority and other aggressive behaviors to younger siblings (Menesini, 2010). Gender differences are another factor, which may be involved in bullying among siblings. Studies report that sisters generally exhibit more affection towards other siblings. Thus, sisters have a lower potential to produce bullying behavior compared to brothers (Menesini, 2010). Additionally, children with conduct disorder (CD) can have a higher potential to produce aggressive behaviors and often project this aggression onto siblings. Children diagnosed with CD usually exhibit repetitive serious aggression and anti-social behaviors, which include threatening others and their property (Mash & Wolfe, 2010).

Prevention of bullying among siblings has equal urgency to those in public settings described above. Parental discipline practices play an essential role in reducing bullying behaviors within the family (Kokkinos & Panayiotou, 2007). Adopting the methods of behavior modification can be effective in eliminating bullying behaviors. In some cases, when parents notice bullying behaviors at home, they might seriously punish their child or children with corporal punishment, such as spanking. Although corporal punishment can produce short-term effects on eliminating children's bullying behaviors (see related chapter, this volume), it leads to long-term increases in bullying behavior (Kazdin, 2001). When parents physically punish the bully, the punishing behaviors provide a model for the child to imitate. Furthermore, punishment from parents can also lead to a strong reaction on the part of the child. Specifically, defiance theory suggests that if children perceive the punishment as reasonable, they are likely

to be compliant; on the other hand, when children perceive the punishment as unfair, they might become offensive and aggressive (Ttofi & Farrington, 2008).

Compared with corporal punishment, positive reinforcement and time-out procedures are more successful at preventing bullying. Parents need to establish the rules for the bullying behavior in the family. If the child does not produce aggressive behaviors towards siblings for a certain period of time, he or she may be rewarded appropriately. Positive reinforcement and time-out are more likely to shape a child's desired behavior than physical forms of punishment in the long-term.

Multi-systemic therapy (MST) also can be considered an effective method to prevent bullying between/among siblings. Instead of relying solely on parents' supervision, MST expands the sphere to a larger social system, including family, school, clinic and associated social organizations (Swenson, Henggeler, Taylor & Addison, 2009). A child with bullying behaviors should be supervised by parents at home as well as teachers and peers at school. Through learning appropriate coping skills from teachers and through peer interactions, a child can be more adaptive in the surrounding social environment. If necessary, children who have expressed themselves through bullying behaviors might require counseling and/or treatment by professional clinicians. A great number of studies have indicated that MST is highly effective in reducing children's aggressive behaviors and improving family relations (Mash & Wolfe, 2010). These behaviors among children, whether at home, in school, or over the Internet, often progress through the child's life. This can carry over into the workplace.

WORKPLACE BULLYING

Bullying is traditionally a concept that people relate to scenarios of childhood and school. This is not the only place that bullying occurs. Workplace bullying is not a new phenomenon but it is one that has recently become the focus of research and public attention. We can extend the definition of bullying at school and home to *workplace bullying*, which is any behavior, conscious or unconscious, that causes another person to feel victimized, humiliated or distressed (Hauge, Skogstad & Einarsen, 2010). Unlike the playground or hallways, however, bullying behaviors in the workplace very rarely are physical but they can cause a drop in job performance (Harvey, Heames, Richey & Leonard, 2006).

Harvey and associates (2006) identified seven different types of bullying behavior found in the workplace and include the following: (a) stigmatizing the victim or pointing out differences between the victim and the bully or the bullies in-group; (b) blaming failures of any kind on the victim, either as an act to humiliate the victim or to simply protect the bully from blame of failure; (c) sexually harassing the victim; (d) singling out someone and placing unreasonable pressure and/or deadlines on one person unequally in comparison to others; (e) isolating the victim by withholding information or opportunities that may be afforded to others; (f) setting up the victim to fail, constantly reminding the victim of past failures and avoiding giving credit to the victim when credit is due; (g) and physically abusing the victim.

Prevalence rates for workplace bullying have been found in one study to be as high as 53% of the respondents who reported being bullied and 77% witnessed bullying during their working career (Rayner, 1997), although most numbers are more conservative and vary between 7 to 10 percent. Research has shown that both sexes are almost equally as likely to be bullied, whereas

some studies show women to have a slightly higher prevalence rate of victimization as men (Rayner, 1997; Harvey et al, 2006). Victims often are in staff positions, as opposed to managerial or executive positions, or they are new to their position or location within the company or new management has recently been put into place (Rayner, 1997). Youth is another characteristic that victims of workplace bullying often share, as the bullied victims are usually relatively young, compared to their coworkers (Rayner, 1997).

Among most victims in the worksite, low self-esteem seems to be a common factor. Victims appear to be less socially confident and competent (Harvey et al, 2006). They are usually more submissive and passive as well. In some cases, they may even be combative when put under social pressure. These factors can combine to make them appear weak or as easy targets for bullies. Because these traits are relatively stable over their lifetime, those who are victims of bullying in school are at higher risk for being victims of bullying in the workplace (Harvey et al, 2006; Matthiesen & Einarsen, 2007). In a small number of situations, victims might actually become an equal rival to the bully. In these cases, the situation is more of a fight for dominance rather than a traditional bully/victim situation (Harvey et al, 2006).

Although it appears that both sexes are equally victimized by bullying in the workplace, the sex of the bully seems to be dependent on the sex of the victim. Women report being bullied equally by both sexes, whereas men rarely report being bullied by women (Rayner, 1997). One explanation for this finding can be found within the definition of bullying. For an act to be considered bullying, the victim must feel like they have little or no control and/or feel threatened. Traditionally, men might not see women as threatening, and those who do might be reluctant to report it as such, because of socialized gender norms where “reporting” would be perceived as a weakness (Rayner, 1997).

Bullying in the workplace has consequences that are similar to those experienced by the victims of childhood incidents with a few exceptions. Experiencing bullying within the workplace can lead to depression and anxiety and in severe cases post-traumatic stress disorder (Hauge, Skogstad & Einarsen, 2010). Workplace bullying also has been found to be related to later long-term sickness and work absenteeism (Ortega, Christensen, Hogh, Rugulies & Borg, 2011). Although these impacts affect people on an individual level, they also have a strong connection to the organization in which they are occurring. All of these things can lead to more frequent sick-days, lower job satisfaction, and decreased productivity. These are all important reasons for organizational leaders to take notice of workplace bullying behaviors and work to reduce or eliminate them. Regardless of where the bullying takes place, multiple problems are associated with the act of bullying.

PROBLEMS CAUSED BY BULLYING

Victims of bullying often come into contact with short-term and/or long-term negative effects, which can range from physical and psychological health problems; at the extreme they can become fatal (Ttofi & Farrington, 2008). Bullying causes serious harm to a student’s social life. Pre-school and elementary environments tend to be the place where children are first labeled as being a bully or a victim. Serious physical harm is rare among elementary students but becomes more common in middle school and high school. Middle school is often the time period when students start to discover self-identity and identify the social groups that may

continue throughout their experiences in the education system and as an adult. These social relationships can develop a significant sense of group affiliation and is crucial among teens because these social circles can help to defend against anxiety caused by social rejection or isolation (Carney, Jacob & Hazler, 2011).

Psychological problems caused by bullying are not limited to only the person persecuted but also are found in bullies themselves, who often suffer from more psychiatric symptoms than other students of the same age. Studies have shown that bullies have a higher rate of psychosomatic symptoms, are more likely to say that school is not an enjoyable place to be, and continue to dislike the environment they encounter in future educational settings (Ttofi & Farrington, 2008). Victims are likely to say that they are unhappy and feel as if they are not safe at school. They are more likely to have higher rates of absences and poor academic success (Hutzell & Payne, 2012). Both male and female bullies and the bullied are likely to suffer from higher risk of depression, anxiety and suicidal ideation. Female victims often have eating disorders as well as depression and feelings of self-worthlessness (Chapell et al, 2006). These risks have a direct impact on the students' physical and emotional health in multiple ways. Symptoms of feeling nervous, sleep deprivation, loneliness, helplessness and agitation are very common among bullied victims and can lead to themselves becoming the bully-victim. Those who suffer from these symptoms are more likely to be submissive, withdrawn, and isolated when compared to other youth their own age (Ttofi & Farrington, 2008).

Bullying can result in long-term social, emotional and psychological effects that can continue throughout the victims' lives. They tend to have poorer social skills, which makes it harder for them to adapt to new situations and environments as they progress forward within an educational system (Farmer et al, 2007). Both the persecutor and the victim involved are more likely to start smoking, have poorer academic standings and display a stronger requisite for social acceptance, unlike those who are not involved (Richard et al, 2011). Bullies with psycho-social deficiencies who show a clear need are often referred to programs that offer assistance. These programs can help by providing counseling and psychotherapy to address problems and to prevent aggressive behaviors (Hutzell & Payne, 2012).

RECOMMENDATIONS TO REDUCE BULLYING AND ITS EFFECTS

Throughout the years, bullying has expanded from schoolyard scuffles to online harassment and it can even follow one into professional worlds. With current variations in the forms of bullying that take place, many prevention programs have been established to help guide individuals and to expunge inappropriate or threatening behaviors. These programs also have been developed to not only purge negative behaviors but to also help individuals to learn correct conduct or to learn how to handle negative situations in better ways. These programs are allowing people to not only prevent bullying but also to be prepared for whatever might come their way in all aspects of life.

As bullying increases in hallways and on playgrounds, many schools have set-up programs to make the environment safer for students. These programs have been implemented to control and reduce school bullying. In 1983, Norway created the first national anti-bullying program implemented anywhere in the world. Evaluation of the program showed a dramatic decrease of about one-half the cases of victimization after the intervention (Ttofi & Farrington, 2011).

Many other nations then started to develop their own programs for training individuals, based on publicized success rates.

Ttofi and Farrington (2011) have reviewed the KiVa Program developed in Finland, which used Internet and visual learning platforms to change student attitudes about bullying. KiVa included devices that allowed an enhancement of their anti-bullying education program, including the use of role-playing exercises, short films on bullying, classroom discussions and group work. Another plus was that teachers were given vests that enhanced their visibility, while they were watching students in the schoolyard. Ttofi and Farrington (2011) also stated that the program included peer support groups for victims of bullying and cooperative group work among experts in dealing with children involved in bullying. Parents were given information and advice about bullying. This program proved that taking simple steps, such as involving teachers and parents, in preventing bullying can cause effective outcomes.

Another recommendation to help with bullying is that children should always have someone to turn to, including psychologists and school nurses. Although school psychologists are limited and have historically focused on assessment and individual treatment in the schools, an incredible opportunity exists for them, as well as others, to function as prevention specialists to help schools determine appropriate assessment tools and to guide intervention planning, implementation and evaluation (Leff, 2007). Another prevention program is the Solving Problems Together Foundation, which provides students with an opportunity to increase critical thinking and problem-solving skills while they work simultaneously toward a solution in dealing with problems (Hall, 2006). This model provides students with a sense of empowerment and allows them to take charge of their own problems. The process behind the program is that students analyze their situations and problems and then seek appropriate resources to help them. Hall (2006) stated that the main purpose of this program is to allow students identified as victims of bullying to develop effective strategies for responding to this behavior. The main goal of this program is for students to go through the problem-solving process so that they can determine strategies that can use when they are facing a difficult situation and/or bullying behavior. This program has many positive effects associated with it, including the development of better problem solving techniques.

With competition in the workplace becoming harder, individuals will resort to anything to get ahead, including lying, wrongfully blaming others and even physical violence. With many of these problems becoming more and more prominent in the workplace, companies and individuals have resorted to developing and implementing programs that will help make their businesses not only happier places to work, but also stronger businesses in general. One prevention step being developed and implemented in workplaces is Anti-bullying Policies. These programs are being implemented in hopes of producing a positive, high-care workplace environment. A bill informally referred to as "The Healthy Workplace Bill" has been introduced across the United States in 16 states since 2003 (Duffy, 2009). This bill has different versions depending on the state, but the bill holds both individual employees and their employers liable for any form of demonstrated workplace harm. Duffy (2009) stated that the bill provides for employer incentives to develop preventive measures and respond adequately and promptly to allegations of workplace bullying. In the long run, this discourages the likelihood of frivolous law-suits. As supported by the bill, placing more programs into the workplace allows not only the employees to benefit from the positive aspects of it, but also the employers because awards they will benefit from when they implement measures that have been supported and specified in this bill.

Another prevention program developed for the workplace is the Three-Step Strategic Program (Namie & Namie, 2009). This program consists of moderation/mediation, coaching and organizational development. The moderation stage is used to allow parties to move beyond any kind of misunderstanding or misperceptions, while mediation is the conflict resolution process. The second part of the program consists of a coaching strategy. This part is mainly supportive, which can fall into inter-personal emotional, career development, or skills enhancement. The third intervention strategy is organization development. Many sources of bullying can be found in attributes of the organization, including reporting relationships, layers in the hierarchy and equitable processes that match rewards to performance. Organizational development defines problems as systemic and suggests that solutions must necessarily affect all people at all levels of the organization. The three-step program has many positive aspects that can result in controlling many kinds of negative problems in the workplace. The first stage allows for affected individuals with the opportunity to explain their perception of the situation, which can prevent rumors and other problems from spreading. The second stage allows individuals to seek support, which helps individuals to work through tough situations. The last stage allows for equal treatment among all employees no matter the status or position that they may hold.

CONCLUSION

Bullying is a devastating occurrence that almost everybody has experienced and/or witnessed at least once in their lifetime. Its presence can be seen in schools, within the home between family members, on the Internet and media devices, and even in the workplace. This aggressive behavior is not prone to any specific individual, but it is often shown to be aimed at people with specific characteristics and lifestyles. Often those who are bullied are seen as being weak or frail, and those who committing the act of bullying are often seen as dominant, powerful and frightening. Both the bully and the bullied might suffer from negative physical and/or psychological consequences associated with their acts, which can have both short-term and long-term effects. Some of these effects range from depression, anxiety and low self-esteem to life-threatening physical damage and even suicide. Although effective programs have been implemented and are successful in reducing bullying within these settings, its variable practices still occur daily worldwide.

The presence of programs within educational systems works, not only as a way to stop bullying on jurisdictional school property, but also to prevent it from occurring after the students have departed from school and are in a working environment or when they have children of their own. As bullying often goes unnoticed, those who are bullied do not know how to deal with their situation. They tend to have feelings of being alone and shy away from any help that is offered. Prevention programs are working to reach out and offer help to any individual or group that feels threatened in any environment. Overall, bullying is a treacherous occurrence that is hard to stop. It is slowly decreasing due to these specialized programs within the educational settings, home and workplace. Parents are becoming more involved, as well as faculty and administrators in schools and administrators on college campuses, to help stop bullying from occurring. Positive attitudes and active reinforcements are the key in producing a more successful and progressive environment for all those involved in bullying.

SEXUAL, PHYSICAL AND PSYCHOLOGICAL AGGRESSION LINKED TO NEW MEANS OF COMMUNICATION: CHILD PORNOGRAPHY, CYBER- GROOMING AND CYBER-BULLYING

Sébastien Prat^{1,*} and Carol Jonas²

¹Forensic Department, University Hospital Center of Tours, France

²Psychiatry Department, University Hospital Center of Tours, France

ABSTRACT

New means of communication have made it easier to communicate worldwide. They enable contact in real time, irrespective of distance and borders. However, these new means of communication have been diverted from their primary use to feed deviant fantasies or to satisfy a need of superiority. There are particular situations that can directly affect people: child pornography, grooming and cyber-bullying. The Internet is the main tool that is used in these three situations. However, the extensive use of cell phones should not be overlooked. In all three situations, the essential factors that explain the growth of offences are virtual aspects of communication and anonymity. Apart from child pornography, the main victims of cyber-grooming and cyber-bullying are adolescents, as, by definition, the victim must be able to establish virtual contact with an aggressor and thus have the capacity to master telecommunication tools. Likewise, the appeal of these tools for adolescents inevitably leads to their deviant use by other young people who are not always aware of the danger of virtual contacts and do not always recognize the impact of bullying. Criminal and victim profiles have been identified. De-materialized aspect of these offences makes it difficult to apprehend the perpetrators. States must take steps to deal with cyber-criminality. New methods need to be set up to apprehend the perpetrators and protect the victims.

Keywords: Internet, child pornography, cyber-bullying, cyber grooming, offender, victim

INTRODUCTION

Changes in society have led to significant shifts in behavior. New electronic means of communication enable messages to be sent instantaneously anywhere in the world and reach a very large number of people (Çetin, 2011). This has had an impact on both sexual violence and other forms of aggression, such as bullying. The victims are usually minors, who are not always aware of the dangers of the Internet and are unable to restrict their use of this tool, which they see as an important social asset (Bryce, 2009). These new means of communication help young people develop social relationships and allow them freedom of thought (Quayle, 2011). For the aggressors, use of these methods is linked to recurrent online contacts with reduced offline social relationships; the anonymity provided by these tools gives them an impression of domination (Appel, 2012). Three particular offences mediated by virtual communication are of particular concern: child pornography, online grooming, and cyber-bullying. Child pornography and online grooming are both sexual offences. However, child pornography does not necessarily lead to contact with an actual victim, unlike online grooming and cyber-bullying, which involve a specific link between the aggressor and the victim. Each of these three behaviors has its own specific characteristics, both by nature of the offence and profile of the perpetrators and the victims.

CHILD PORNOGRAPHY

Child pornography is the production of pornographic or erotic material involving use of children or adolescents (Chase, 2005; Howitt, 2007; Taylor, 2001). Tackling this phenomenon is complicated, owing to the range of child-pornography material and the diversity of criminal justice proceedings in different countries (Endrass, 2009; Kierkegaard, 2008; Prat, 2012, 2012a; Tirelli, 2008; Tyler, 1985). The first photographs go back to 1862 (Tyler, 1985). For many years, child pornography was limited to written texts and photographs (Burke, 2002; Frederick, 1996). Some aspects were perceived as artistic. In France, for example, Tony Duvert received a literary award in 1972 for his book "*Paysage de fantaisie*," which can be perceived as an *apologia* for child pornography. Technological progress has gradually increased the possibilities of representing pedophile fantasies. Not only did the arrival of the Internet assist revised production of child pornography, it also allowed it to be disseminated more widely. It was not until the end of the 20th century that various nation-states began to pass laws to deal with the problem (Tyler, 1985).

Characteristics of Child Pornography Images

Actualization of child pornography is reprehensible. At present, no court has penalized pedophile fantasies, as long as they are not disseminated. Child pornography is a lucrative market. It mainly involves photographs and video recordings. Some written texts exist, but these generally accompany an image. The law had to be changed at the beginning of the 2000s to counter the growing industry, owing to use of new electronic means of communication and technologies (Prat, 2012). These new technologies facilitated the production and dissemination

of pedophile images. The specific characteristic of this practice lies in the content of the images. As explained above, it does not necessarily involve a pornographic picture. The COPINE Project or *Combating Paedophile Information Network in Europe Project* drew up a classification of images, based on their suggestive or actually sexual aspects, also adding notions of sexual violence (Krone, 2004; Quayle, 2000; Quayle, 2006; Taylor, 2001; Taylor, 2003). Ten different types of image were identified, which varied in the degree of violence of the fantasies: 1) *Indicative*, 2) *Nudist*, 3) *Erotic*, 4) *Posing*, 5) *Erotic posing*, 6) *Explicit erotic posing*, 7) *Explicit sexual activity*, 8) *Assault*, 9) *Gross assault*, 10) *Sadistic-Bestiality*. Other aspects of these images should be considered, notably the fact they do not necessarily involve real aggressions. There is in effect a scale of images (Mirkin, 2009; Tate, 1992).

There are also so-called virtual or pseudo-photographs, created from collages or by computer graphics (Kleinhans, 2004; Krone, 2004). This aspect raises legal problems, as creating these images does not involve any actual abuse. Additional legal measures were thus introduced to tackle the issue. In many cases, people make large collections of images. In 1992, Lanning described six characteristics of child-pornography collections (Taylor, 2001): 1) *size* (number of images), 2) *consistency* (a specific topic), 3) *organization* (image classification), 4) *permanence* (preservation over time), 5) *secret nature* (images kept safe in protected places), 6) *sharing* (images pooled on pedophile sites). These images constitute an effective bargaining chip between child pornographers, who form networking groups to exchange advice, or find a minor. Interest in the images does not lie in stimulating fantasies, but rather in their use as a means of networking between collectors, of disinhibiting children for online and offline contacts, of rationalizing the adult's deviant behavior, and in some cases performed for financial gain (Quayle, 2003; Quayle, 2006; Taylor, 2001).

Child Pornography Users

A number of authors have described the profiles of child-pornography users. Generally, classifications mix simple child pornography users who do not contact a minor with people who solicit minors on the Internet with the intent to make contact online or offline. Burgess and associates (2005), for example, identified three categories: 1) *Traders* (people who collect child pornography via the Internet), 2) *Travelers* (people who seek to communicate with children), 3) *Traffickers* (people who participate actively in child trafficking with the aim of exploiting them sexually). Elliott and associates (2009) described four typologies: 1) *Periodically prurient* (people who show curiosity but without any actual sexual interest in children), 2) *Fantasy only* (people who are content with gratifying their fantasies virtually, without any real or virtual contact), 3) *Direct victimization* (people seeking real or virtual contact with minors), 4) *Commercial exploitation* (people interested only in the financial aspect). Krone (2004) drew up a more detailed description with eleven categories: 1) *Browsers* (people who come across images by accident, but knowingly save them), 2) *Private fantasists* (people who access images for their own interest and do not wish to share them), 3) *Trawlers-sexually omnivorous* (people who consume all types of pornographic material, including child pornography), 4) *Trawlers-sexually curious* (people who have experimented with child pornography but have not pursued it), 5) *Trawlers-libertarian* (people who believe that they are free to access all types of material), 6) *Non-secure collectors* (people who download and exchange images from openly available sources that do not impose security barriers), 7) *Secure collectors* (people who

download and exchange images, taking precautions to limit the risks of being caught), 8) *Online groomers* (people who use child pornography with the intention of establishing contact with a minor), 9) *Physical abusers* (people who use child pornography both as part of actual abuse and to gratify their craving when they have no actual victim), 10) *Producers* (people who produce images involving either a real abuse, or pseudo-images), 11) *Distributors* (people who supply the pedophile network but who do not necessarily have pedophile fantasies themselves).

From these classifications, we can see that child pornographers, who are mostly seen as users as opposed to producers and distributors, do not use child pornography for the same purposes. Child pornography is not a clear-cut phenomenon and its use varies according to these profiles. One of the main notions to consider is pedophile attraction; a number of authors have shown that images are not always downloaded purely for pedophile sexual arousal (Elliott, 2009; Krone, 2004; Prat, 2012b). In some cases, this type of image is accessed as a way of defying a taboo. In this situation, the individual also displays an interest in other images of violence, war, among others. In general, studies of child-pornography users do not differentiate between people who do or do not establish virtual contact with a minor, even though direct communication adds to the risk of actual abuse. However, there does not appear to be a correlation between consuming pedophile images and the risk of committing an offline offense (Endrass, 2009). By contrast, studies generally differentiate between virtual and real contact (Deirmenjian, 2002; Gillispie, 2007). In sum, the use of child pornography can either constitute an end in itself or be a means of carrying out an offline abuse.

Typically, child pornography users are almost exclusively educated, professional men between the ages of 25 and 50. Overall, there are as many married users as single. On the whole, they are in a consensual adult sexual relationship, although they might not experience it as satisfactory (Beech, 2008; Burgess, 2005; Burke, 2002; Fortin, 2006; Frei, 2005; Prat, 2012b, 2013; Quayle, 2006). In general, there is no history of previous psychiatric disorder. In most cases, there is no prior conviction for a sexual offense. The rate of recidivism for child pornography users is relatively low, emerging one and a half to six years after conviction (Babchishin, 2011; Eke, 2011; Seto, 2011; Wakeling, 2011). With regard to their psychopathological functioning, we can observe a cognitive distortion, generally similar to that of a pedophile who has committed actual abuse, although they may have more empathy with their victims (Babchishin, 2011; Burgess, 2005; Marziano, 2006; Seto, 2011). This can be explained by the fact that the borderline between the virtual and the real is sometimes tenuous and that many child-pornography users have clearly pedophile fantasies, even if they only gratify them virtually.

Child Pornography Victims

Victims of child pornography can be divided into two categories (Prat, 2013; Varnhagen, 2007): minors who have been subjected to an actual assault and minors whose image has been falsified for sexual purposes (pseudo-images). With regard to distribution of child-pornography imagery, what is important is the process of perpetual victimization (Prat, 2013). Even if the assault actually occurred once or not at all in the case of a pseudo-image, victimization continues indefinitely with the transmission of the image depicting a minor in an erotic or pornographic scene. Moreover, the aggressors can put pressure on victims through the pictures

they have taken, either telling them they must keep it secret or subjecting them to further abuse under threat of diffusing the images (Tate, 1992).

Interpol maintains a database of 520,000 images, involving 680 victims. The Internet Watch Foundation identified 2,755 Internet domains involving child-pornography images. Almost 80% of these images involve young girls (Elliott, 2009). This high percentage of female victims could explain the low rate of recidivism, as a higher rate of recidivism occurs among extra-familial homosexual pedophiles. In the 80,000 photographs and 400 video recordings identified by the COPINE Project, there were as many boys as girls (Quayle, 2000; Taylor, 2001; Taylor, 2003). UNICEF (2009) released a report stating there were more than four million Internet sites and that more than 200 new images were posted every day (Maala, 2009). At the end of 2011, the Interpol database contained 2,500 victims from 46 countries (Aiken, 2011). In general, children of all ages are involved, including infants, pre-pubescent children and adolescents. These categories of victims provide significant psycho-pathological information about the users of these images, notably to setting up appropriate prevention measures (Elliott, 2009). It is the apparent age of the victims in the image that is generally used by the courts to determine whether or not child pornography is involved. In some cases, the images involve adults dressed up as children. Under these circumstances, the protagonist's status changes from victim to accomplice (Prat, 2013a).

The attitude of the victims in the pictures is an important issue. Most images show children looking cheerful or neutral (Burke, 2002). This plays a role in the cognitive distortions of pedophile-customers, as they have the impression that these scenes are not unpleasant for the children, who must be enjoying themselves, reinforcing the idea that there is no coercion involved.

Child pornography is a complex deviant behavior. Users are not always satisfied with "fuelling" their fantasies through the images, but may seek contact with a minor, even if only virtually.

ONLINE SEXUAL GROOMING

Online grooming is a way of establishing contact with another person for sexual purposes. It corresponds to legal practice, when two adults establish a relationship on the Internet to satisfy reciprocal desires and an illegal practice when an adult seeks to satisfy his/her sexual cravings with a minor. There is a close link with child pornography, as pedophile images are often used to establish online and then offline sexual contact (Chase, 2005; Quayle, 2003; Quayle, 2006; Taylor, 2001). The adult may take pictures of the assault, which he can then use later to attract other minors (Prat, 2013). The use of telecommunication devices enables the perpetrator to identify and make contact with a "target" child (Tate, 1990; Taylor, 2003). Before the arrival of the Internet, establishing contact between a pedophile and a minor involved a direct relationship with no way of falsifying identity. The perpetrator used specific means of persuasion to establish a close relationship or resorted immediately to violence. Emergence of the Internet made it possible for the perpetrator to remain anonymous and falsify his identity, thereby making it easier to establish a relationship through online grooming (Burgess, 2008; Quayle, 2003).

Characteristics of Online Grooming

Online grooming developed at the same time as cyber-sex (Quayle, 2003). Development of the Internet made it easier for pedophiles to realize their fantasies. Distance communication made it possible to reach large numbers of people. As mentioned in the Introduction, possibilities of distorting reality provided by virtual contact has a significant effect on the occurrence of online grooming (Deirmenjian, 2002). There are two significant aspects of online grooming. First, it can simply be a means of identifying vulnerable minors that sets the stage for a meeting, without waiting for the minor's consent. Secondly, it can involve establishing a complicit contact between adult and minor, leading the minor to engage in sexual activity with an adult without coercion. When the Internet and virtual communication technologies first emerged, the aggressor had to gain the victim's confidence for the discussion to take on a sexual connotation. Nowadays, with the growth of social networks, very detailed information, including a photograph, enables an aggressors to make more rapid and targeted contacts (Quayle, 2011). In particular, they can target minors living in their neighborhood, thereby opening a possibility of establishing an offline contact faster and more easily. Likewise, personal details make it easier to identify vulnerable minors likely to be more receptive to and less suspicious compliments made by the adult.

Anonymity afforded by the Internet and electronic communication devices is a critical element in *virtual assault*. In particular, it allows identity and age to be collapsed and/or falsified, a method commonly used to obtain the child's confidence. It also has an impact on the aggressor, notably in terms of disinhibition (Quayle, 2003). Various aspects of disinhibition have been identified. For example, Whittle and associates (2012) referred to a study in 2004 by Suler, who identified six underlying factors: 1) *dissociative anonymity*, corresponding to not being identifiable online, 2) *invisibility*, whereby virtual abuse is facilitated by not having to worry about social appearances, 3) *asynchronicity*, whereby the time lag imposed by these methods of communication impairs normal reactions, 4) *solipsistic introjections*, whereby lack of face-to-face communication can allow one person to conjure up a false image of the other with an impression of being able to read their mind, 5) *dissociative imagination*, whereby there is a split between the online and offline *persona*, allowing the abuser to live in a fictional world, 6) *minimization of authority*, whereby the person does not feel that he is committing any offence because there is no real contact.

New means of communication enable instantaneous discussions to take place at a distance. This makes fantasies seem almost real (Quayle, 2011; Whittle, 2012). Two of three profiles identified by Elliott and Beech (2009) can be found among online groomers: 1) *browsers*, who seek to communicate virtually, 2) *cruisers*, who adopt a sexual language in order to establish offline contact, 3) *pornographers*, whose specific interest is in pornographic material, without seeking any personal contact. It is this third profile that corresponds most to the child pornography users whom we have described. However, one should not overlook the impact of child pornography on the functioning of the online groomer, as we have shown with its use for attracting minors (Krone, 2004). This material enables adults to join discussion groups, thereby making it easier to identify minors able to meet their needs. A study in California found that 30% of sexual assaults involved the Internet (Gillispie, 2007). These assaults mediated by the Internet mainly involved men. In most cases, victims were aware that they were communicating with an adult (Quayle, 2011; Wolak, 2008).

Online Groomers

Davidson and associates (2011) defined an online groomer as someone who initiates contact with a child through the Internet with the intention of establishing a sexual relationship, involving cyber-sex or sex with physical contact (Davidson, 2011; Quayle, 2011). The term covers a heterogeneous group, as is generally the case for child sexual offenders (Prat, 2013; Whittle, 2012). Studies indicate that time spent prior to the offline meeting varies, usually around one month. However, it should be noted that in some cases the contact occurs less than 24 hours after the first online discussion (Quayle, 2011). The literature does not provide a specific profile, unlike child-pornography users where grooming does not have a direct sexual aim (Prat, 2012b, 2013). By contrast, two groups appear to emerge: *contact-driven group* comprising people who are looking for a real offline contact and *fantasy-driven group* composed of people who are looking for cyber-sex with no offline contact (Briggs, 2010; Quayle, 2011).

The *fantasy-driven group* like those who download pedophile images (characteristics often found in the same person), unlike the perpetrators of sexual assault, generally show few criminal characteristics (Quayle, 2011). They spend a lot of time on the Internet, which allows them to avoid real social relationships. These virtual contacts allow them to gratify their sexual urges. It is possible that these individuals are inhibited, and/or have a social phobia, explaining the low criminal aspect and low rate of recidivism (Barron, 2000; Prat, 2012b, 2013; Quayle, 2003). This inhibition could thus be considered a protective factor, keeping them away from the risk of carrying out actual abuse. For these individuals, the online contact is a way of gratifying a fantasy that child pornography material cannot do. The characteristics of this group are broadly similar to those of users of child pornography: relatively young with a good education and no criminal record. It is possible that people who consume child pornography gradually become *fantasy-driven*. It could therefore be considered an escalation of the pedophile process, and should thus be treated as a potential risk of offending.

Individuals in the *contact-driven group* target children and then create links with them as a precursor to assault. This method of virtual communication allows them to establish a non-coercive contact (Guan, 2009; Quayle, 2004; Tyler, 1985). The non-coercive aspect of an assault on a minor is an important element. In fact, not all child sexual offenders act with violence and force. Some seek the child's approval, as part of their way of operating. Pedophile attraction can in fact be linked to other cognitive distortions, such as the impression the act is not deviant and the child is willing (Babchishin, 2011; Burke, 2002; Howitt, 2007; Marziano, 2006). Indeed, some pedophile groups militate for release of people imprisoned following a sexual relationship with a minor not involving coercion (Tyler, 1985). Their argument is based on the child's consent. The difficulty in explaining this consent, even when it is clearly expressed by the child, is biased first by the child's emotional immaturity and secondly by the possibility the child is psychologically disturbed. Online groomers are generally younger than offline offenders (Babchishin, 2011; Prat, 2013). This can be explained by the recent emergence of these means of communication. Previously, in order to gratify fantasies, offenders had to find their victims in the real world. They therefore set up specific mechanisms to attract victims, such as showing an interest in children living in the neighborhood, obtaining their parents' confidence, among other tactics. As these mechanisms work for them, they have not needed to change their behavior. Now, thanks notably to the Internet, pedophiles can be more circumspect

and can establish contact without having to communicate with people close to the child, making it more difficult to identify and apprehend them (Krone, 2004).

Victims of Online Grooming

Victims of online grooming are generally adolescents between the ages of 14 and 17 (Willis, 2002). This can be explained by the fact the victims must themselves be connected to the Internet and know how to use it. Within the general population, between 13 and 17 percent of children have been victims of online solicitation (Whittle, 2012). Half the children reported these events to an adult (Varnhagen, 2007). Wolak and associates (2004) found that one child in seven who used the Internet had experienced a sexual solicitation; 4% were aggressive and 34% involved exposure to pornographic material. These children must be able to understand objectives of the adult, particularly when the latter seeks to establish a sexual contact without coercion. Unfortunately, it is very likely that the average age of the victims will fall in coming years due to the fact that the Internet is being used by increasingly younger children and there is a certain form of liberalization of behavior, as parents do not always restrict access nor monitor their children's interactions. The victims are generally psychologically distressed (Willis, 2002). They often have self-image problems that can be linked to previous abuse or flawed family structure. They are more likely to respond to advances made by individuals who often offer comfort. They are therefore willing to establish a relationship, particularly if it boosts their self-esteem, which no other person has done. These children can then become victims of child pornography, if they are filmed or photographed during their abuse. Fortunately, as pointed out by Wolak and associates (2008), not all children who use the Internet are at risk.

The advent of social networks has changed the identification and profile of potential targets. Previously, victims were approached in online *chat rooms*. Contact was established around a particular topic in which the child participated. The groomer showed a passing interest in this topic in order to establish a special relationship with the child, pretending to share a common interest. Increasingly, with the rise of social networks, children seek to extend networks to prove their popularity, driving them to reveal information about themselves without worrying about potential risks. Giving personal information, particularly details that enable a child to be located, which could lead to sexual discussion, incurs a greater risk of receiving aggressive messages and of suffering an offline assault (Mitchell, 2007; Quayle, 2011). Furthermore, some messages left on the child's personal page describe her/his distress and hence vulnerability. Fortunately, this concerns a low percentage of children, as observed by Quayle and Taylor (2011) quoting a study by Ybarra and associates (2007). A study by Dowell and associates (2009) reported that 20% of adolescents who put photos on line were at risk (Dowell, 2009).

Online grooming has a real psychological impact, even if no actual abuse occurs. The other type of cyber-violence involving a real victim is cyber-bullying.

CYBER-BULLYING

Bullying is a wide-spread phenomenon found in all areas of social life and affecting people of all ages. Underlying factors motivating this behavior are complex. Like the two offences described above, the use of new means of communication has transformed this phenomenon. Previously, harassment or intimidation involved specific characteristics, such as need for a victim, an aggressor and a bystander. Now, the bystander is no longer systematic and yet impact is just as great. Bullying tactics were rarely possible without a real contact. When leaving school or the work-place, the victim could feel a sense of security, because of the absence of the aggressor, whereas now these destabilizing tactics lack boundaries and there can be no refuge. Moreover, the fact that messages are sent anonymously renders them even more destabilizing, and the victims do not know which way to turn.

The Characteristics of Cyber-Bullying

Olweus (1995) defined bullying through three criteria: 1) showing aggressive behavior towards an individual or group, 2) it is repetitive, 3) there is a clear power imbalance between “bully” and “victim” (Baughman, 2012; Huang 2010; Kowalski 2007). A fourth criterion can be added, namely, 4) the intention to harm the victim (Baughman, 2012). Cyber-bullying removes the physical aspect, leaving only the so-called verbal (insults, rumors) and emotional (exclusion, social alienation) aspects of the aggression (Çankaya, 2010; Kowalski, 2007). In traditional bullying, physical aggression could be a major component with some bullies using insults to provoke a victim to react violently. Bullying involves distinct behaviors: direct insults, indirect insults, exclusion, rumors. There is a difference between cyber-stalking and cyber-harassment. In cyber-stalking, the victim fears a credible threat likely to result in real physical injury. Cyber-stalking thus provokes more psychological disturbance and is more difficult to put aside than cyber-harassment (Dimond, 2011). Cyber-bullying can be broken into indirect and direct aggressive behavior. Direct aggression harms the victim without attacking them personally, for example, sending hoax messages, indecent photos or making threats. Indirect aggression no longer consists of physical assault but involves disseminating personal information or spreading false rumors, which can have a direct impact on the victim's reputation (Betz, 2011). Most studies on cyber-bullying involve cohorts of adolescents and/or students. Few studies have described the practice of cyber-bullying among adults. Children who bully or become victims of bullying are generally over ten years of age, which is related to the use of electronic means of communication such as the Internet and cell-phones that have become a popular way of aggressing someone close, especially among young people. Before advent of these devices, the main places where bullying occurred was school or university. This geographical limit of bullying provided a degree of emotional protection in that the victim had a possibility of avoiding these places. Now, the specificity of cyber-bullying has removed these temporal and spatial boundaries. The victim can thus be reached at any time – at school, university, work or home.

The Internet has modified the forms of bullying but the number of bullies does not seem to have increased (Dimond, 2011; Kumazaki, 2011). By contrast, the specific nature of these new means of communication is that it enables virtual relationships, whereby some adolescents only

know each other through the Internet. Addiction to the Internet seems to encourage the spread of cyber-bullying, associated notably with a reduction in social relationships (Çankaya, 2010). Thus, as stated above, it is sometimes impossible to identify the aggressors, and even when they are known, they remain intangible, leading to a sense of estrangement, and dispossession of the self (David-Ferdon, 2007; Stassen Berger, 2007). In a study by Li (2007), half the students had already heard of someone being cyber-bullied. It is a well-known but underestimated, phenomenon. In a study carried out by Patchin and Hinduja (2006), 11% of participants had been aggressors, 29% had been victims, and 47% witnesses. In some ways, this phenomenon is similar to malicious calls in that it involves repeated, anonymous attacks.

With regard to the actual organization of the aggression, there remains the question of the form that it takes. At what point can one consider oneself the victim of aggression? When it involves a repeated message, notably on social networks, does a message posted by the same individual constitute a new aggression, or is it part of a single aggression? If someone else takes part in the conversation, are they considered to be a second aggressor? (David-Ferdon, 2007). Initially, bullying required the existence of a group. People could harass an individual alone, but in this case the profile was generally one of gratifying sadistic urges, while the main characteristic of bullying is that the aggressors feel superior in the eyes of peers by belittling another person. With cyber-bullying, the power of the aggressor is no longer a question of physical strength or notoriety, but lies rather in the possibility of constantly harassing someone with no restriction of time or space. Phenomena have thus emerged that could be described as individual, in that the aggressor no longer requires a group to find satisfaction in the harassment which now only involves two people. Group cyber-bullying exists, notably through open discussions on social networks, which have enabled traditional offline bullying to be recreated on the Internet.

Cyber-Bullies

The perpetrators of cyber-bullying, mainly children or young adults, generally show relationship difficulties with their parents. There are two types of bully: those who bully gratuitously to gain notoriety and those who bully as a reprisal and can thus be described as bully-victims. The latter often react impulsively to a previous real or imagined aggression. Among adolescents, this tends to concern boys more than girls, with the reverse trend among adults (Stassen Berger, 2007). Girls have a greater tendency to reveal secrets and spread rumors, while boys generally have more direct, less insidious behaviors (Çetin, 2011; Huang, 2010). Unlike girls, boys tend to attack people of the same sex (Betz, 2011). Finally, these behaviors seem to overlap and can occur offline, where boys show proactive aggressive behavior, while girls behave in a more indirect fashion. Anonymity increases the power of the aggressors, who therefore feel stronger (Çetin, 2011). Wolak and associates (2007) observed the proximity that is often found between the aggressor and his/her victim; in 57% of cases the aggressor is a known peer and in 43% of cases is unknown. The impact on the victim is generally underestimated by the perpetrator due to the online contact and the lack of physical aggression.

The virtual aspect of this aggression has modified the profiles of bullies. Some are described as inhibited, without social ties, and generally addicted to the Internet, at the same time needing stimulation and personal satisfaction that they find through harassment, notably for the sense of power it gives them (Kowalski, 2007). Previously, bullies were described as

people certain notoriety in their group. Their behavior was never explained as possible psychological disorder. Now, there is concern about psychological disorders shown by these bullies and cyber-bullies, notably narcissistic disorders and suicidal ideation (Betz, 2011; Kubiszewski, 2012). Aggressive behavior such as harassment does indeed reflect a mental disorder that can only be externalized by attacking others.

There appears to be a link between the aggressive attitude of a child and the likelihood that he/she will become a bully in adolescence. An aggressive child is generally rejected, while an aggressive adolescent is often feared and respected (Stassen Berger, 2007). Behavior that can be a manifestation of mental suffering thus becomes a solution for finding notoriety and respect, and it is therefore difficult for the bully to stop this apparently beneficial behavior. The role played by the other peers is critical in the way the bullying behavior develops. Some bystanders can easily become bullies themselves, thinking that it will bring them notoriety or simply as a way of pleasing the aggressor. This phenomenon is found in cyber-bullying where there is not always an audience, but when an aggressor can find personal satisfaction in the action this brings an impression of narcissistic aggrandizement. It was initially thought that bullies had problems with social skills, which explained their behavior. Baughmann and associates (2012), however, demonstrated they had good scores on social intelligence, notably with capacities for empathy that made their intimidation more effective. By contrast, what emerged were anti-social traits. Bullies also have better scores on social cognition tests than victims and observers, which enables them to anticipate the behavior of others (Baughman, 2012). However, in some cases, an individual may act merely in a spirit of revenge in the anonymous environment afforded by cyber-space which appears safe and secure, thus becoming a cyber-bully in response to previous offline harassment (Baker, 2010).

Victims of Cyber-Bullying

There is a continuum in the process of victimization between bullying and cyber-bullying. David-Ferdon and associates (2007) found that 68 to 97 percent of online victims were offline victims, and between 2 and 76 percent had experienced physical violence. Two categories of victim have been identified: *passive* and *aggressive*. *Passive victims* are generally weak and submissive. They have few relationships with peers, very low self-esteem, which reinforces the intimidation, but good contact with adults, both parents and teachers. They often have the fatalistic impression that these people will not be able to help them, giving the aggressor a powerful hold over their defense mechanisms. *Aggressive victims* on the other hand are impulsive. They generally have previous psychological disorders that give rise to stigmatization, which is the starting point of the harassment. They adopt ineffectual reprisal behavior but find no support among adults (Stassen Berger, 2007). As in conventional harassment, aggressive victims will attempt to retaliate, but their impulsiveness may aggravate a situation, as they do not realize the impact of new communication such as the Internet. Their response may thus be out of proportion with the initial aggression, and the image they present is thus more that of aggressor than victim.

The virtual aspect has given rise to a third category, corresponding to victims who could be defined as neutral and who are sometimes chosen at random. At the outset, these victims do not present any psychosocial characteristics associated with vulnerability or any physical or psychological features that could give rise to stigmatization. The fact they become victims is

due to their reaction to the aggression. The principal behind bullying and cyber-bullying is its repetitive nature. The way the victim reacts will thus either give credit to the rumor or encourage the aggressor to repeat the malicious messages.

Many psycho-social problems have been identified among victims of bullying and cyber-bullying, including stress, depression and social anxiety, declining academic performance, narcissistic disorders among girls and delinquent behavior among boys (Baughman, 2012; Kubiszewski, 2012). The prevalence of depression is three times higher than that reported in the general population (Baker, 2010). Some victims have even been found at school with a weapon, which appears to be the only way they can feel safe. These problems can be treated readily with strong family support, determined effort to stamp out the process, particularly when the child seeks the help of an adult. In a study by Wolak and associates (2007), 12% of the victims told their parents of the incident and 9% told another adult. There are several causes for this lack of communication with parents. First, there may be difficulty confiding in a parent linked to the typical conflicts found during adolescence. Another factor that is frequently reported in the scientific literature concerns the child's fear their use of the Internet will be restricted, because they consider this means of communication so essential for well-being (Appel, 2012). In half the cases, it seems that the child is also afraid the parent may make the situation worse. In general, although it is not always effective, the child will seek support from his/her peers. Only peers who are popular within the child's social group can help stop the harassment (Fenaughty, 2012). The most effective criterion to stop this phenomenon is for the child to seek the help of an adult more than actual assistance, by adopting a passive attitude (Fenaughty, 2012; Stassen Berger, 2007). Other strategies used to tackle the problem appear to be ineffective, such as passively ignoring it, or confrontation, which merely seems to boost the bully's ego and stimulate aggressiveness (Fenaughty, 2012).

Over and above the possible help of others, the victims' own characteristics will affect their ability to extricate themselves from an aggressive situation. They must have sufficient social skills to identify risky situations, know how to get rid of messages, and alert the people who are in a position to help them (Betz, 2011). In a study by Smith and associates (2004), 72% of victims had stopped being victims two years later, because they had been able to modify their social environment. For a person no longer to be considered as a victim of cyber-bullying, two criteria must be met; first, bullying behavior has effectively stopped, and second any psychological disorders caused by the behavior have disappeared. While bullying has been modified by cyber-phenomenon, main targets are still the most vulnerable people on account of physical appearance or psychological vulnerability. An inability to overcome psychological disorders, linked to bullying, will lead to the long-term continuation of these disorders, and will aggravate the victims' vulnerability, making them more susceptible to future attack. The term *cyberbullicide* was coined to describe suicide, influenced by virtual intimidation (Betz, 2011). It is not always easy for victims to escape from the harmful environment when cyber-bullies act via a communication tool that is indispensable to their victims, even if the latter have good social skills (Dimond, 2011).

Cyber-bullying is the ultimate non-sexual cyber-aggression. It includes a wide range of behaviors, whose negative consequences are not always immediate.

CONCLUSION

New electronic means of communication have opened up considerable changes in terms of violence, notably the emergence of *virtual violence*. In some cases, virtual violence can lead to very real physical and sexual abuse. The other feature inherent in the virtual aspect concerns attacks that can be qualified as “hidden.” Some victims of child pornography know nothing about dissemination of their image as part of a pedophile fantasy. Likewise, victims of online grooming are not aware of the other person’s sexual interest in them and victims of cyber-bullying do not always know the identity of their attacker. Development of these offences has therefore required specific measures. Speed and ease of communication, together with lack of frontiers, has obliged many countries to change existing or create newer legislation. With regard to cyber-bullying, this offence does not generally cross national borders. Legal procedures in contrast to deal with use/distribution of child pornography and online grooming, two very similar practices, had to be modified, as the networks frequently involved several countries. Various police actions, notably by Interpol and Europol, have led to the arrest of members of some networks (Dombrowski, 2004; Gillespie, 2010; Kierkegaard, 2008; Krone, 2005; Prat, 2012a). However, certain police practices, notably sting operations, are allowed in some countries but not in others.

These three deviant online behaviors mainly affect children. They lead to what can be called ‘rebound’ or ‘time-bomb’ phenomena (Bryce, 2009). The aggression is not always immediate, the victim is not always aware of it and it has delayed psychosocial consequences. The general public must therefore be made aware of these phenomena and the very real risks to young people of using electronic means of communication in general, and the Internet in particular.

Chapter 135

FROM THE TRENCHES: CYBERBULLYING AND BEYOND

Conor Mc Guckin^{1,*} and Lucie Corcoran²

¹Trinity College Dublin, Dublin, Ireland

²Dublin Business School, Dublin, Ireland

INTRODUCTION

We are living in the future
I'll tell you how I know
I read it in the papers 15 years ago
(John Prine: Living in the Future)

Welcome to this collection of state-of-the-art writings on cyberbullying. The title of this opening chapter alludes to three things. Firstly, that we are in a war and fighting from the trenches - where hand-to-hand fighting occurs - up close and personal with the enemy. We believe that some of the intervention and prevention work in the area of cyberbullying has been exactly this - hasty approaches to fighting an enemy that caught most of us off guard - perhaps being aware of the potential threat - but not the intensity or frequency of it. The second issue is that we are dealing explicitly with cyberbullying. The authors present a timely critique of the area - from definitional issues to intervention and prevention approaches. In a relatively short space of time, we have been flooded with the positive aspects of the Web 2.0 technological and digital revolution. Even more so, we have been faced with the ever evolving menace of bullying behaviours that utilise these new technologies and media. Thirdly, we want to encourage you to consider the lessons learnt from the initial emergence, and ongoing experience of, cyberbullying. That is, as you read these critical reviews of the literature, we want you to speculate about future developments in the area. In particular, we believe that it is worth taking heed of the messages in these chapters for the days and years ahead, as we see another important issue on the horizon - the rapid growth in the development and implementation of artificial intelligence and robotics. As an ethical and civil society, it is our duty to learn from the past,

* Corresponding Author's Email: conor.mcguickin@tcd.ie.

account for the present, and plan effectively for the future. We can always hope for the best, but we should plan for the worst. So, as the chapters aid our understanding of cyberbullying, the things we have learnt and have done well (or not so well), as individuals with an interest in how to protect childhood whilst encouraging creativity and imagination in the modern world, we do need to lift our heads from the sand and look to the unknown future – to plan ahead for the children yet to be born.

FROM “TRADITIONAL” BULLY/VICTIM PROBLEMS TO CYBERBULLYING ... AND BEYOND

Just as we were getting used to “traditional” bully/victim problems, albeit differentiated across different contexts (e.g., f2f: Mc Guckin, Cummins, & Lewis, 2010; alterophobia: Minton, 2012; disablist: Purdy & Mc Guckin, 2014, 2015), each with a substantive canon of knowledge regarding prevalence, actor status, correlates, and intervention approaches, along came cyberbullying. From an initial stance of widespread denial by school leaders about bully/victim problems occurring in their schools, even the best regulated schools now admit that such problems exist among the pupils in their care. The focus has now become about who is involved, what are the consequences on educational and personal growth and attainment, and how its insidious nature can be ameliorated.

Tim Berners Lee’s Internet and the World Wide Web, whilst being arguably the most open form of communication to evolve since the Cro-Magnon’s development of cave drawings and linguistic ability that separated them from their Neanderthal predecessors (Corcoran, Mc Guckin, & Prentice, 2015; Drogin & Young 2008), is perhaps also one of the most anonymous. Indeed, considering the very fundamentals of the technology - ownership and regulation - Berners Lee has advocated for an online Magna Carta/Bill of Rights in this area (Kiss, 2014). In the absence of such control or regulation, to what extent can we rely on children and young people (and adults) to use the technology in this modern “wild west” (Corcoran, Frazer, & Mc Guckin, 2015) for positive benefits only? If we accept that the experience of being human is fraught with a continual dichotomy of “good versus evil,” then we need to also accept the responsibility of helping fellow humans make pro-social choices in relation to the use of this great technology. As alluded to, the emergence of artificial intelligence and robotics as significant areas of technological growth and employment, brings with it the “potential” for new areas of concern - could the perpetrators of bullying behaviours include not only humans and virtual avatars, but also humanoids? Indeed, we could argue that, in a transhumanism advance, most of us already fit the criteria of being a cyborg (cybernetic organism: Clynes & Kline, 1960) - that is, whilst we talk about smart“phones,” the reality is that most of us use these devices for telephone calls far less than for all of the other means of connectivity made possible by their technological capabilities. The sheer extent to which these devices are part of our daily life and engagement with routine day-to-day tasks (e.g., remembering birthdays, anniversaries), we have fears now of issues related to “digital dementia” (Mc Guckin, 2014).

In a very short period of time, humanity has evolved from the significant advances of the agricultural revolution, through the industrial revolution, to the recent digital revolution. Even though the very real and positive advances of the digital revolution have yet to be fully explored, or indeed experienced by all members of society, we are already involved with the

Internet of Things (IoT) and newer technological discoveries and applications for the advancement of society and human experience – e.g., the CRISPR interference technique in genetics (clustered regularly interspaced short palindromic repeats) (Qi et al., 2013) that means that gene editing is now as simple as “copy and paste” on this word-processor I am using, and blockchain distributed databases that will become pervasive in terms of ensuring security of online transactions and cryptocurrencies (e.g., Nakamoto, 2008). For all of us with an interest in the protection of children and young people, we have to work hard and fast to keep abreast of these developments.

Whilst Moore’s Law (1965) predicts the exponential growth of technology, specifically computer processor power, the emotional repertoire of children still develops in the timeless manner in which our own emotional capabilities developed. Unlike technology and computing power, we do not have similar “laws” with regard to children’s development, still relying heavily on the assumptions of lifespan development theories (e.g., Freud, Piaget, Erikson, Kohlberg). The unenviable task that society has challenged us to, is to think, research, and act in the same manner as Moore and colleagues - to help future-proof our children and their children in time to come. We must accept this challenge. We must also embrace the challenge and prove our worth as researchers, practitioners, and fellow citizens.

We do not have the luxury of sitting on the side-lines admiring the shiny new technologies. Rather, like the pioneering theorists and researchers before us, we must feel free to “think aloud,” to “stop and stand and stare,” and encourage each other that it is okay to make mistakes in our thinking and logic (e.g., Dweck’s [2006] Growth Mindset). Success, unfortunately, does not come without a pathway of failed ideas and faulty logic. Even with the advances of neuroscience, we can still find lots of examples of “faulty logic” in the hypothesised implications and applications of these new findings and discoveries for educators and classrooms (Doyle & Mc Guckin, 2016).

As the Nobel laureate Samuel Beckett (1983) encourages us: “Ever tried. Ever failed. No matter. Try again. Fail again. Fail better” (p. 7). As researchers and practitioners in this area, it is our duty to accept Beckett’s encouragement and to never see the work to be done as a Sisyphean task. The authors of the chapters in this book have certainly seized the task and are constantly seeking the new information that we need in order to ameliorate the insidious and obnoxious effects of bully/victim problems mediated through these new, and still to emerge, technologies. As you read through the chapters, we would again encourage you to think widely about the issues raised, remembering that we do not have to be responsible for the problem to be responsible for the solution.

CHAPTERS AND FOCUS

Chapter 2: How Research on Cyberbullying Has Developed

An obvious and interesting question that many readers might have is exactly how much research has been completed in the area. It is this query that Peter Smith and Fethi Berkun explore in their fascinating portrait of the area. This work is a great contribution to the literature. Just as the later chapter on definitions challenges us to consider how we “talk about” and conceptualise the issues of concern, Peter and Fethi’s chapter provides us with an opportune

reflection on “where we have come from” and “where we have arrived at,” after 15 years of activity. We enjoyed reading the analyses in Peter and Fethi’s chapter, perhaps summed up as “lots done, more to do.” We hope that this chapter provides some impetus for new research studies and challenges that need to be surmounted (e.g., longitudinal designs) if we are to impart really robust evidence to colleagues designing or implementing prevention/intervention programmes.

Chapter 3: Conceptual and Definitional Issues Regarding Cyberbullying: A Case for Using the Term Cyber Aggression?

At the start of any discussion in the social sciences, researchers should “operationally define” the key concept(s) of concern to the work. All too often, however, this does not happen and the reader can be left with an ongoing internal debate as to how the central issues should be defined - perhaps in law, in practice, or just in terms of inclusion/exclusion criteria for the various audiences that we seek to inform. A small number of years ago, the community of those with an interest in the emerging issues that were to be called “cyberbullying” debated and worked collaboratively to explore how this new issue should be defined - should it be a natural extension of the definitions associated with traditional bully/victim problems, how to include reference to the new technology - and the technology that does not yet exist, etc. In their chapter, Pauline Hyland, John Hyland, and Christopher Alan Lewis present a timely review of the interesting developments in this area - from initial and perhaps “blunt” definitions to more nuanced definitions that emerged as knowledge and thought in the area matured. Whilst most of the research regarding traditional bully/victim problems has operated from largely the same definitional criteria (i.e., intentional harm doing, repeated actions, imbalance of power), work in this new area of cyberbullying requires consideration of extra factors - e.g., 24/7 aspect of the digital world, a different focus for what “repeated” means in this new context. Bringing us right up-to-date, the chapter explores whether we should consider “cyber aggression” as a more appropriate conceptualisation of the issues.

Chapter 4: Prevalence Rates of Cyberbullying from a Cross-National Perspective: Definitional and Methodological Issues

Irene Connolly helps us to understand the prevalence of cyberbullying from a cross-national perspective. Irene rightly points out that research in this area is constantly evolving, partly due to a response to developments at a societal and technological level, and also at a research level, where understanding of the nuances involved in definitions and methodologies are becoming more mature. Of necessity in a chapter like this is an introduction to the development of the definitions used and subsequent methodological issues that enable us to intelligently decipher these prevalence rates. What becomes evident throughout Irene’s chapter is the development of thought and understanding within this important area - e.g., the critical debate that Peter Smith and Dan Olweus encourage us to consider - the extent to which traditional and cyberbullying are either sufficiently different from each other in terms of those

involved or at a more conceptual level. What is evident is that merely trying to present a cross-national perspective on prevalence rates is less than straightforward.

Chapter 5: Cyberbullying among Children and Adolescents: A Quantitative and a Qualitative Approach to Gender Differences

Raúl Navarro, Santiago Yubero, and Elisa Larrañaga reflect upon gender issues and cyberbullying - from childhood through adolescence to college. This is a timely chapter that explores that “old chestnut” of gender differences in aggression. Whilst such differences always exist, the real challenge is to explore the nuances involved. As society becomes even more heterogeneous and accepting of differences between individuals, this chapter serves to caution us about our previous thinking about how aggression is mediated via gender construction. Whilst it used be considered that girls were not aggressive, the research community eventually included girls in research studies of aggression. Within this new paradigm, we saw that girls were not really aggressive. However, the flaw in this approach was that girls were be assessed against a set of theoretical and operational criteria that were, essentially, male-focused (e.g., physical aggression). Considering that the major thinkers in the field of aggression were predominantly (if not nearly exclusively) male, this error becomes contextualised. With the situation rectified in the early 1990’s, we developed a more fine-grained understanding of female aggression, with it becoming understood that girls and boys were aggressive in a “quantitatively” similar manner, but in “qualitatively” different ways. Raúl and colleagues have been researching this area and provide a timely and up-to-date review of how we currently conceptualise gender and how cyberbullying is experienced through this important variable; challenging some of the possible stereotypes that may be clouding our perceptions. Interesting in this chapter too is the new quantitative and qualitative data that the authors share from their research among children and young people in Spain.

Chapter 6: Re-Thinking Well-Being Measures in Bullying and Cyberbullying Research

Jolanta Burke and Stephen Minton give us a lot to consider in their thought provoking chapter. We can probably accept that through much of psychology’s history, we have had a focus on the negative side of human experience. Whilst this is not necessarily wrong or misguided, and has often been necessitated by societal developments (e.g., WWII and the subsequent research of compliance, conformity, and obedience) or the requirements of an ethical science (e.g., quasi-experimental studies of acquired brain injury, aftermath of significant and unexpected trauma), there has, until relatively recently, been a neglect of the positive side of human experience. Couched within a positive psychology perspective, Jolanta and Stephen explore approaches to well-being. The importance of this chapter is to challenge us to consider how we can usefully modify our research efforts in this area if we are to really work towards prevention and intervention approaches that are successful in protecting our children and young people.

Chapter 7: Physical Proximity, Social Distance, and Cyberbullying Research

Whether you are new reader to this area or not, Stephen Minton provides a chapter that really is “food for thought.” Stephen excels as not only a significant researcher in the areas of bully/victim problems and cyberbullying, but critically adds to our knowledge in this fast paced research and applied environment by taking time to “stop and stand and stare.” That is, Stephen excels in thinking and theorising about these issues (e.g., alterophobia: Minton, 2012). We are thankful to Stephen for this work, as detractors from outside the area seek to criticise research in this area as being atheoretical. In this chapter, Stephen asks us to consider the evolution of theory and action regarding human aggression - from the seminal work of Lorenz in ethology, to the work of Milgram on post WWII issues of concern regarding compliance and conformity to authority figures. This notion of “distance” - both physical distance and social distance is explored through Stephen’s chapter, and argued as important criteria to be cognisant of when considering the new parameters of human aggression via technological means - i.e., cyberbullying. Stephen brings together a previously disparate literature to show us, and to remind us, not to forget highly important theoretical concepts, empirical research findings, and the societal issues that we should never forget - e.g., Auschwitz, Zimbardo, dehumanising language, bystander effect, genocide, native American Indians, and moral distance.

Chapter 8: The EU Kids Online Project: The Importance of Large Scale Cross-National Research

At an early stage, one of the most welcome developments at a pan-European level was the instigation of the cross-national EU Kids Online research project. In one place, and at one time, we had a considerable amount of rich and detailed information about the experiences and wider familial and societal issues related to what was fast becoming termed the “always-on” (Belsey, 2006) generation. In their chapter, Brian O’Neill and Thuy Dinh provide us with an overview of the work conducted by the consortia and the key messages from the research. Such contextual information has been of great benefit to researchers and practitioners who have sought answers to important questions regarding Internet safety, usage, etc. This work is still salient and highlights the need for such networks and their important recording of information that enables us in our need to monitor, interpret, and understand the lives of our children and young people.

Chapter 9: Cyberbullying in South Korea

Historically, research and interest in bully/victim problems was largely from a European perspective, with interest later developing further afield (see Smith et al., 1999 for a very interesting and classic cross-national perspective). With the emergence of US based research in the area, the research literature grew with this body of new knowledge. We would argue that, amidst this heightened interest and awareness, it became more difficult for colleagues in other parts of the world to have their voices heard. Again, Smith et al.’s (1999) book gave us critical insight to the work of colleagues in the Australasia region. In her chapter, Seung-ha Lee gives

us a very important review of the development and current state of cyberbullying in South Korea. This chapter identifies the issues that are different for children and young people in South Korea, and the approach being taken to counter the various issues and types of cyberbullying discussed.

Chapter 10: Needs, Determinants, Coping, and Stand-Alone Interventions

Health and well-being (physical and mental) are always of concern when we explore issues such as cyberbullying. Francine Dehue, Trijntje Völlink, and Nicole Gunther explore these issues in the context of needs, determinants, coping, and stand-alone interventions. Of particular interest in this chapter are the linkages made with the need to help and support children and young people. The linkages are made between successful coping strategies and the development of programmes aimed at helping children and young people. Francine and colleagues review some of the programmes that have demonstrated usefulness, whilst also pointing out that much work is still needed to address the requirements of effective evidence-informed approaches.

Chapter 11: Coping with Cyberbullying

Having been actively researching the issues regarding coping with cyberbullying over the last number of years, Lucie and I have worked on a chapter that explores the theoretical views of coping and how we have been able to develop knowledge of how children and young people cope with cyberbullying – from technological coping strategies to personal strategies. Like many of the variables associated with the experience of being involved in cyberbullying, the issues regarding coping are more intricate than a casual perusal of the literature might suggest.

Chapter 12: Cyberbullying and Mental Health: Internet-Based Interventions for Children and Young People

As part of the increasing risks and community fears regarding children and young people and cyberbullying, many attempts have been made at developing prevention and intervention approaches to the issue. Whilst we see a review of these efforts in this book, what is often missing - not just from prevention/intervention programmes in the field of cyberbullying - but from many programmes that address risk factors among our children and young people, is attention to health and well-being. Nicole Gunther, Francine Dehue, and Viviane Thewissen introduce the concept of e-mental health and encourage us to be more cognisant of the possible additive effect of including such approaches in our explorations of cyber related issues amongst children and young people. For example, they point out that many children and young people will not identify cyberbullying as a factor when discussing their issues with parents or health professionals.

Chapter 13: The Australian Perspective: Efforts to Counter Cyberbullying

Research studies exploring bully/victim problems among Australian children and young people has had a long and important history. In 2005, Marilyn Campbell published her “old problem in a new guise?” paper, and demonstrated that Australian society and research community were well aware of the dangers associated with new technologies. In the last number of years, Australian researchers have continued to advance knowledge in key areas regarding cyberbullying - from papers exploring definitional issues, to prevalence, and intervention studies. In her chapter, Marilyn provides us with an overview of these contributions, as well as issues regarding the media, the law, and teacher education.

Chapter 14: Teachers’ Perceptions of Cyberbullying in Irish Secondary Schools

Much research in the area has explored the experiences of children and young people. In a quest to get as much knowledge on prevalence figures, correlates, and the overlap with traditional bully/victim problems, not as much attention has been directed at the adults who support and care for these young people. If we are to encourage educators to be the “upstanders” for pro-social behaviour in educational settings, and to implement prevention and intervention programmes, knowledge of their attitudes and perceptions is critical. This has been demonstrated in relation to disablist bully/victim problems by Purdy and Mc Guckin (2014, 2015), where one-third (35%) of student teachers reported that they would deal with incidents of disablist bullying using “natural instinct.” Caroline Wheeler reports upon her research among a sample of Irish teachers. With the knowledge from this study, and other studies that have sampled adults, we can move further towards a position whereby the adult carers and supporters of children and young people feel confident in their knowledge of the issues.

Chapter 15: Concluding Thoughts: Where Are We Now and Where to Next?

To conclude, Lucie reflects upon the chapters and their messages. In doing so, Lucie also looks to the future, a future that will surely change through more technological developments. As we move towards that unsure future, we all have the same goal in mind – to help preserve the normality of human growth and development, and to protect children and young people from harm and harassment.

Chapter 136

HOW RESEARCH ON CYBERBULLYING HAS DEVELOPED

Peter K. Smith* and Fethi Berkkun

Goldsmiths, University of London, England

INTRODUCTION

The origins of the term cyberbullying have been discussed and also researched by Bauman (2011). She points out that its first use is often ascribed to Bill Belsey. Belsey was moderating a website on general bullying prevention, and as young people were starting to describe being bullied online, in 2003 he created a website at www.cyberbullying.ca. However, Bauman found a few earlier uses of the term, the earliest apparently being a New York Times article about cyber addiction in 1995.

The term cyberbullying, and indeed Belsey's use and website which may have sparked the wider adoption of the term, suggests a relationship to bullying generally. As has now been well discussed, cyberbullying can be seen as a new, additional form of bullying. There is clearly substantial overlap with what is now often called traditional bullying, both conceptually, and in terms of who is involved. But the overlap is far from complete in either respect. Conceptually, the particular characteristics of cyberbullying challenge or stretch the usually accepted definition of bullying, in terms of the repetition and imbalance of power criteria. In terms of who is involved, because cyberbullying is not face-to-face it can involve persons who rarely or never see each other in offline situations. In addition, the disciplinary nature of research on cyberbullying shows new aspects. Research on traditional bullying has mostly come from developmental psychologists, and some from sociologists. Cyberbullying has also attracted more attention from disciplines such as media and communications, information technology, and legal studies.

Cyberbullying has certainly impacted on the study of school bullying, which has been a major research program developing since the 1970s. Smith (2014) suggested that there have been four main phases in this. The first, from the 1970s-1988, covered the origins of research,

* Corresponding Author's Email: p.smith@gold.ac.uk.

notably with Olweus' (1978) book *Aggression in Schools: Bullies and Whipping Boys*, and his development of a self-report questionnaire. The period from 1983-1985 saw the first major school-based intervention program, in Norway; the success of this inspired the next phase of research. The second phase, from 1989-mid 1990s, saw surveys being carried out in many countries; in addition peer nominations methodology was developed. Interventions started taking place in other countries, beyond Norway. Also, the definition of bullying (as with aggression generally) expanded to include relational and indirect forms, notably social exclusion and rumour spreading. The third phase, from mid 1990s-2004, saw school bullying established as an international research program. The development of participant role scales by Salmivalli and colleagues was an important innovation. Surveys, and intervention work, were now reported from many countries around the world. The fourth phase Smith (2014) dated from 2004, with the growth of cyberbullying. Although cyberbullying had origins before 2000, most press reports and awareness of the issue date from around 2004, initially with text message and then email bullying, but now taking many forms.

Smith's comments were based on experience of active research in the area since 1989, rather than on any systematic review. Zych, Ortega-Ruiz, and del Rey (2015) reported a more systematic study of publications on bullying and cyberbullying, from 1978 to 2013. They used the Web of Science and selected journal articles on school bullying, which explicitly referred to and were concerned with bullying (including cyberbullying). Due to the great number of such articles, they took the 10 most cited articles in each year (or all, if less than 10), resulting in 309 articles. These comprised 233 on traditional bullying and 76 on cyberbullying. They divided the content of these into: (a) nature and dynamics, (b) related variables, (c) minorities, and (d) prevention and intervention.

Zych et al. (2015) found the earliest articles on cyberbullying in 2003, with just four articles before 2006. To analyse time trends they therefore divided their analysis of cyberbullying articles into the two periods: 2006-2010 and 2011-2013. Of 42 articles sampled in the 2006-2010 period, 28 were on nature and dynamics, and 14 were on related variables. Of 30 articles from 2011-2013, this switched around with 11 on nature and dynamics, 17 on related variables, and two on minorities. None of their cyberbullying articles were scored in the prevention and intervention category.

Zych et al. (2015) also counted the number of authors of each cyberbullying article. Comparing the same two time periods, the mean number of authors increased from 2.74 to 2.87. The percentage of articles with international collaboration (two or more country affiliations in the authors) increased from 14% to 20%. The US, followed by Canada and the UK, provided the most articles.

The work of Zych et al. (2015) provided a valuable sketch of how research on bullying, including cyberbullying, has developed. However they only examined the 10 most cited articles each year. This means that the picture they present is of the most influential research at the time of writing. Nevertheless these articles are only a small fraction of the total, and so this does not give a full picture of the kinds of research being carried out and reported in peer-reviewed publications. They also only included articles on school-age bullying; but cyberbullying especially is more permeable to age distinctions. We decided to build on the work of Zych et al. (2015), focusing just on cyberbullying but in greater detail. We aimed to examine the abstracts of all journal articles, rather than just the most highly cited ones, and to include lifespan studies as well as those on school-age participants. We also extended coverage up to 2015.

METHOD

Following Zych et al. (2015), we used the Web of Science database to extract details (title, authors, and abstracts) of articles on cyberbullying. We made the following searches: cyber* and bully*; cyber* and victim*; electronic bullying; Internet bullying; and online harassment.

Table 1. Categories used for coding abstracts on cyberbullying, at step 1 and step 2

Step 1 (n = 538) Year of publication Number of authors (when occasionally not clear from the Abstract, this was checked with the full article) National affiliation of authors (when occasionally not clear from the Abstract, we checked with the full article) Type of article - Opinion piece/no data - Narrative review - Meta-analysis - Original empirical data
Step 2 (n = 454) Articles that presented original empirical data were scored for the presence of any of the following: - Discussion of definitional or measurement issues - Longitudinal data - Qualitative data - Prevalence figures - Age comparisons - Gender comparisons - Country comparisons - Disability/minority group/data or comparisons - Other risk factors or correlates of involvement (e.g., personality, empathy) - Outcome variables (e.g., health, well-being, internalizing or externalizing symptoms, suicide) - Peer group factors, social dynamics, bystanders - Parents - Siblings - Teachers - Coping strategies - Legal issues - Resources and interventions

We started the search from 1990. However from 1990 to 1999 we only obtained 6 abstracts; these were all judged irrelevant at initial screening (they either were brought up by different aspects of “electronic” and “bullying,” or referred to electronic attacks on company brands). We then searched the period from 2000 up to 2015 on a yearly basis, delaying the 2015 sampling until mid-March 2016 to ensure a nearly complete record for that year.

For further analysis we used the following inclusion criteria: Academic journal article; Abstract at least is in English; Article is focused on cyberbullying, victimization or harassment, or has this as a major part. We had corresponding exclusion criteria: Book, book chapter, non-academic article, conference proceedings (in conference proceedings we included *Procedia* articles; the *Procedia* website states that “The *Procedia - Social and Behavioral Sciences* does not have, and is not eligible for, an Impact Factor as it does not publish primary research, full length, peer reviewed articles”); No abstract or text in English; Article does not mention cyber bullying, victimization or harassment, or else has it as quite a minor part of the main objectives (for example, only one of five or more topics or measures examined).

Following this procedure, we obtained a total of 538 eligible Abstracts over the 16-year period, an average of 33.6 per year. We then proceeded to code the Abstracts in two steps, using the categories shown in Table 1. In step 1 we coded all of the Abstracts. In step 2 we carried out further coding of 17 categories for those articles reporting original empirical data.

The coding was discussed extensively between the two authors, and the codes clarified where necessary, with any doubtful codings being discussed jointly. The codings are only based on the Abstracts, as examining all the full articles in detail was beyond the timespan of this project. This is a limitation; some codings might only be apparent from the full article, for example “gender comparisons” might have been reported, but not mentioned in the Abstracts. The Abstracts did vary considerably in terms of their quality and apparent coverage. However, being limited to Abstracts also has an advantage in that it highlights the main thrust(s) of each article as thought of as important by the authors. This seems appropriate for an overview of the development of the sub-discipline, such as this chapter aims to provide.

RESULTS : STEP 1 ANALYSES

Year of Publication

Although the average number of articles per year was 33.6, this built up from a very slow start during the first seven years of this century, but then increasing rapidly. The year 2015 saw 131 articles, meaning about 2.5 new articles every week. The change on a year-by-year basis is shown in Figure 1. The figure suggests three broad phases in terms of volume of research published: (a) from 2000 to 2006, a small trickle of articles (range 0 to 5 per year); (b) from 2007 to 2011, a substantial but still modest number of articles (range 10 to 38 per year); (c) from 2012 on, a very large number of articles (range 85 to 131 per year). Since 2009 the trend has been steadily upwards, with no sign of a plateau. For purposes of later analyses of time trends, we made 3 groupings of year periods: (a) from 2000 to 2011 ($n = 125$); (b) 2012-2013 ($n = 180$); and (c) 2014-2015 ($n = 233$).

Figure 1. Number of cyber bullying articles by year of publication.

Number of Authors

The overall mean is 3.11 authors per article. However, there is a steady increase over time in number of authors, from 2.66 for 2000-2011, to 3.00 for 2012-2013, and rising to 3.42 for 2014-2015.

National Affiliation of Authors

We started this analysis by looking at the lead (first author) national affiliation of authors. The USA ($n = 161$) provided the largest contribution, followed by South Korea (52), Canada and Australia (36 each), UK and Spain (35 each), Turkey (27), Germany (21), Belgium (19), Italy (17), Netherlands (15), Taiwan and Sweden (9 each), Israel (6), Finland, Switzerland, New Zealand, and China (5 each), Czech Republic and Singapore (4 each), Denmark, Japan, and Hong Kong (3 each), Austria, Portugal, Norway, and Nigeria (2 each), Estonia, Poland, Luxembourg, Malaysia, Brazil, Colombia, Croatia, Cyprus, India, Ireland, Lithuania, Serbia, Slovenia, France, South Africa, and Thailand (1 each).

For purposes of further analysis, we grouped lead author national affiliation by continent. This yielded North America ($n = 197$), Europe (including Israel) ($n = 190$), Asia (including Turkey) ($n = 106$), Australasia ($n = 40$), and Other (Africa and South America) ($n = 5$).

Continental affiliation by year period is shown in Figure 2. North American contributions predominated in the first period, but with an equally substantial contribution from Europe since 2012. Contributions from Asia have been increasing markedly, and there has been a steady contribution from Australasia.

Examining mean number of authors by continent, this was highest in Europe ($n = 3.54$), followed by Australasia ($n = 3.15$), then North America ($n = 2.97$), and Asia ($n = 2.58$).

Cross-National and Cross-Continental Research

The preceding analyses are by first (lead) author, so numbers are equivalent to number of articles. Many articles featured researchers all from the same country. However we also looked at how many articles featured authors spanning more than one country and also more than one continent.

Out of the 538 articles, 29 (5%) had authors from more than one country within a continent, and 36 (7%) had authors from more than one continent (of these, 4 articles had authors from different countries within and continents). Of the 29 cross-country (within continent) articles, 24 were within Europe. Of the 36 cross-continental articles, 27 involved North America, 20 Europe, 14 Australasia, and 13 Asia.

Figure 2. Continent of lead author by grouped years.

Figure 3. Type of cyber bullying article by grouped years.

Type of Article

The great majority ($n = 454$) of articles provided original empirical data. We classified a much smaller number as opinion pieces ($n = 45$), narrative reviews ($n = 33$) or meta-analyses ($n = 6$). Figure 3 shows trends in these, by year period. There is a steady increase in empirical articles. Review articles (either narrative or meta-analyses) are more noticeable in the last four years.

RESULTS : STEP 2 ANALYSES

The number and percentage of articles scoring in each of our 17 categories are shown in Table 2. The four largest (all over 30%) are “Other” predictors of involvement (i.e., beyond age, gender, country, minority group), outcomes of involvement, prevalence rates, and gender differences. We examined each category in relation to both year period (2000-2011, $n = 105$; 2012-2013, $n = 150$; 2014-2015, $n = 199$), and continent of lead author (North America, $n = 163$; Europe, $n = 159$; Asia, $n = 96$; Australasia, $n = 33$) (Other, $n = 3$, was not included in analysis). Where there was a clear and sizeable difference, by year period or by continent, we refer to this in the Discussion.

Table 2. Numbers, and percentages (out of n = 454) of empirical data articles scored in each of 17 categories, based on abstracts

Category	Number	Percentage %
<i>Definitional or measurement issues</i>	31	7
<i>Longitudinal data</i>	24	5
<i>Qualitative data</i>	30	7
<i>Prevalence rates</i>	172	38
<i>Age differences</i>	73	16
<i>Gender differences</i>	163	36
<i>Cross-national comparisons</i>	15	3
<i>Minority groups</i>	29	6
<i>Other predictors of involvement</i>	257	57
<i>Outcomes of involvement</i>	207	46
<i>Peer groups, Social dynamics, Bystanders</i>	89	20
<i>Teachers</i>	25	6
<i>Parents</i>	55	12
<i>Siblings</i>	9	2
<i>Legal issues</i>	7	2
<i>Coping strategies</i>	35	8
<i>Resources and interventions</i>	39	9

DISCUSSION

The findings of our analyses confirm some trends reported by Zych et al. (2015), but extend these to articles on cyberbullying generally (not just the most highly cited articles), and to two more recent years, 2014 and 2015. In fact the last two years provide 43% of the total number of articles. Figure 1 illustrates the dramatic rise in the number of articles, especially over the last five years. The research area of bullying generally has also shown a sharp rise this century (Olweus, 2013), but cyberbullying has clearly contributed significantly to this growth from 2012 onwards.

The earliest articles came from the US (as noted by Zych et al., 2015), and indeed North America predominated in the early years of cyberbullying research (Figure 2). This contrasts with research on traditional bullying, which originated in Scandinavia in the 1980s (with a separate tradition on *ijime* in Japan) (Smith, 2014). Traditional bullying research became active in many European countries from the early 1990s, but in North America some years later. North American work initially referred to peer victimization and harassment (Juvonen & Graham, 2001), but the bullying concept soon came to be widely used, and Espelage and Swearer (2004) were able to provide an important collection of research in American schools. Interestingly cyberbullying does not appear in the index of these contributions, although it no doubt existed (Bauman, 2011). Soon after this, the first relevant publications on cyberbullying were appearing, sometimes referred to as Internet harassment (e.g., Ybarra, 2004).

Although North American research provided the main initial contribution in the cyberbullying area, the volume of research in Europe has grown more rapidly, and has overtaken North America in the last four years. One factor here is likely to be sources of funding

through the EU Framework programs. Programs such as DAPHNE (on child and family safety issues) generally require that several different European countries collaborate, and Europe has provided the majority of cross-national (but within-continent) articles, and the highest number of authors per article (3.54 compared to 2.97 in North America). The COST IS0801 Action on Cyberbullying, which ran from 2008 to 2012, brought together 28 European countries in networking activities, and led to many publications (see Smith & Steffgen, 2013).

Research in Asian countries has also been significant, and is increasing rapidly (Figure 2). Major players here have been South Korea and Turkey. The high number of abstracts obtained from South Korea ($n = 52$), compared to for example Japan ($n = 3$), may of course reflect whether an English language abstract is provided by the journal (we picked up many Korean journals doing this). Turkey ($n = 27$) was also involved in the COST project. Finally, research in Australasia has been at a steady rate, modestly increasing and sizeable given the population of the countries involved. However, to date, research from Central or South America, and Africa, has been very limited.

The rapid rise in research publications has of course paralleled the rapid rise in penetration of ICT amongst the population generally and especially young people. Surveys such as Kaiser Foundation (www.kff.org) and Pew (www.pewinternet.org) in the USA and Ofcom in the UK (www.ofcom.org.uk) have demonstrated how availability and use of mobile phones and computers has increased dramatically this century, with a rapid increase in Smartphone use since around 2011. New journals, such as *Cyberpsychology, Behavior, and Social Networking* (1998-), *New Media & Society* (1999-), and *Cyberpsychology: Journal of Psychosocial Research on Cyberspace* (2006-) would have facilitated the growth in English-language publications (Livingstone & Smith, 2014). There have also been many special issues of mainstream journals on the topic of cyberbullying (e.g., *Australian Journal of Guidance and Counselling* 20(2), 2010; *Emotional & Behavioural Difficulties* 17(3-4), 2012; *European Journal of Developmental Psychology* 9(2), 2012; *Journal of Community and Applied Social Psychology* 23(1), 2013; *School Psychology International* 33(5), 2012; *Zeitschrift für Psychologie/Journal of Psychology* 217(4), 2009).

Naturally, the great majority of journal articles have been providing original empirical data. A relatively small number of articles in academic journals were classed as opinion pieces, for example discussing conceptual or practical issues without providing any data. The number of review articles in journals is also small, but growing over the period with meta-analyses beginning to appear in the last few years to help make sense of the vast amount of findings now accumulating (Figure 3).

Types of Research

Definitional or Measurement Issues

This category covered both studies of definition (such as which criteria are recognised as important for deciding if an incident is cyberbullying), and measurement issues (such as reporting on the design, reliability and/or validity of a questionnaire). These have appeared at a fairly constant rate of around 7% of articles, over the three time periods.

Definitional issues are still debated, with some researchers preferring to use the concept of cyber-aggression more generally; see Bauman, Underwood, and Card (2013) and Smith, del Barrio, and Tokunaga (2013) for different views on this. An example of an empirical study

(originating from the COST Action on cyberbullying) is a six-country cross-national study by Menesini et al. (2012, 2013), in which 11-17 year olds were given scenarios and asked to judge whether they were cyberbullying, or not. Scenarios varied according to the presence or absence of various criteria. Imbalance of power was found to be the most important criterion, followed by intentionality, and anonymity of the perpetrator (as a substitute for imbalance of power); less important criteria were repetition, and also the public/private nature of the context.

Measurement issues also remain unresolved. For traditional bullying, although there are many instruments available, the Olweus Bully/Victim questionnaire has held some position as a widely recognized and used instrument, also adapted for cross-national surveys such as carried out by HBSC (Currie et al., 2012). This is not the case for cyberbullying. There is a plethora of instruments, each often used in just one or two studies, and many with shortcomings. Systematic reviews of 44 cyberbullying instruments by Berne et al. (2013) and Frisé et al. (2013) found that many did not give adequate definitions (only 13/44 mentioned imbalance of power) and few reported their reliability or validity. Reference periods and cut-off points varied. Similar findings were reported by Vivolo-Kantor et al. (2014).

Longitudinal Data

Longitudinal studies make up around 5% of the total, increasing however from only 1% in the 2000-2011 time period to 6% and 7% in the two more recent time periods. Although nearly half (46%) of all empirical articles report on outcomes, the great majority of such studies have been cross-sectional. These can present a *prima facie* case for outcomes, but any causal inferences between involvement in cyberbullying and, for example, internalizing or externalizing symptoms, will only begin to be convincing when longitudinal data is available. Even then, data over a series of time points (rather than just two) are highly desirable (Braun, Kuljanin, & DeShon, 2013).

Qualitative Data

Most empirical studies have been quantitative. Studies that included qualitative data (either solely qualitative, or mixed methods) make up around 7% of the total. This has only changed slightly over the three time periods (6%; 5%; 8%). Qualitative data are likely to be most useful when some aspects of the phenomena are under-explored, and thus predetermined survey questions may miss out important aspects of what those involved in cyberbullying are experiencing. Given that cyberbullying is a relatively new area, and also one where the phenomena are changing rapidly, this lack of qualitative studies could be seen as a negative feature of the research program so far. It may reflect the preponderance of psychologists (rather than sociologists, for example) and of researchers coming from work on traditional bullying. Traditional bullying has a long history and has arguably not changed much over decades, so a relative lack of qualitative studies (see Thornberg, 2011), even if unfortunate, is understandable. It appears less justifiable for cyberbullying.

Prevalence Rates

It is natural that prevalence rates appear in many studies (38%), since they will often be reported even when the main focus of interest might be on correlates of involvement, or outcomes. These have included rates for perpetration, being a victim, or more rarely the joint bully/victim role. Prevalence rates vary hugely (Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Modecki, Minchin, Harbaugh, Guerra, & Runions, 2014), even when based on self-

reports of peer bullying/victimization (the most common source). For example, some studies report prevalence rates of around 2-5%, others of 20-30% or more (Hinduja & Patchin, 2012; Olweus, 2012). Reasons for this variation include the nature and age of the sample, the date of survey administration (often not stated!), whether a definition is given and what it covers (criteria such as repetition and/or imbalance of power?), what emphasis there is on particular media or types of cyberbullying, what time reference period is used for occurrences (last month?, ever?), and what frequency cut-off is used for reporting (just once or twice?, or more often?). Overall, it appears that occasional or one-off occurrences may be reported by over 20% of young people but serious or recent or repeated incidents are typically reported by only around 5%.

Not surprisingly, studies reporting prevalence were most frequent in the first time period, at 55% of articles, when the phenomenon was being established. They have fallen to 32% and 33% in the two more recent time periods. They have also been somewhat more frequent in North America (46%) than in Europe (29%).

Age Differences

A specific comparison of age differences appeared in around 16% of articles, largely irrespective of time period or continent of authors. Cyberbullying is a phenomenon that spans age ranges. Ševčíková and Šmahel (2012) gave prevalence figures in the Czech Republic from 12 to 88 years, with a peak for both aggressors and victims in adolescence. The early adolescent peak was confirmed by Kowalski et al. (2014), and Tokunaga (2012) suggested a peak of involvement around 15 years, slightly later than for traditional bullying, perhaps because of the greater technological knowledge involved. However cyberbullying has also been reported in children down to 8 years (Monks, Robinson, & Worlidge, 2013). The increasing penetration of ICT to younger ages may well mean that age differences in cyberbullying change to reflect this.

Gender Differences

A specific comparison of gender differences appeared in around 36% of articles. This is much more numerous than age differences, perhaps because, unlike for age, almost all samples will provide the opportunity for gender comparisons. They have become slightly less frequent over the time periods (40%; 37%; 33%). Gender differences have been found to be very variable across studies (Tokunaga, 2012). They may depend on the type of cyberbullying (for example, girls being more interested in social networking sites, boys more in online gaming; Pew Research Center). But age appears to be another important variable. Barlett and Coyne (2014) examined 122 gender effect sizes from 109 research articles, for cyberbullying perpetration. Overall, they found boys' rates exceeding girls; but this varied by age. Up to early adolescence, girls exceeded boys in cyberbullying perpetration, but by later adolescence, boys exceeded girls. Compared to traditional bullying (where boys predominate), it does seem that girls are relatively more involved in cyberbullying. This is perhaps because girls are relatively more interested in reputation damage as a means of bullying, for which cyberbullying via social networking sites is an obvious forum.

Country Comparisons

Cross-national comparisons have been very rare, at only 3% of articles. They have been slightly more frequent in European studies (5%), perhaps aided by the cross-national cooperation required in much EU funding for research, referred to earlier. While interesting,

cross-national comparisons are difficult to carry out in a reliable and valid way, due to many issues around equivalence of constructs, bias, and language used in translation (Guillaume & Funder, 2016; Smith et al., 2016).

Disability/Minority Groups

Cross-national comparisons have been rare, at only 6% of articles. These have included any comparisons of minorities such as different racial or ethnic groups, or sexual orientation, as well as disability. They have been more frequent in North America studies (10%), compared to other continents (3-4%), perhaps indicating a higher profile of these issues in the US especially. The overall low frequency is perhaps surprising, given the greater risk of cyberbullying involvement that many minority groups experience (Kowalski et al., 2014).

Other Risk Factors or Predictors of Involvement

This emerged as our most numerous category of article, at 57%, even though it was not scored for comparisons by age, gender, country, disability or minority group. Particularly common are measures such as self-esteem, empathy, and personality variables. Risk factors or predictors will be important in developing theories of involvement in cyberbullying, as well as for targeting some intervention procedures. Such studies are somewhat less in the last time period (48%) compared to the first two (64% and 63%).

Outcome Variables

Outcome variables was the second most numerous category of article, at 46%. This covered aspects such as health, well-being, internalizing or externalizing symptoms, and self-harm, suicidal ideation, or suicide. Demonstration of the generally very negative consequences of being a victim of cyberbullying, or of any kind of involvement, is important in harnessing concern for the issue and getting support for intervention and prevention. There is not much variation in such studies by continent or time period, but unlike predictors, they are not decreasing in recent years (49%) compared to earlier time periods (43%; 43%). Most studies have been cross-sectional, but as noted above, the small number of longitudinal studies has shown a modest increase in recent years.

Peer Groups, Social Dynamics, Bystanders

About one-fifth (20%) of studies have included some focus on the peer group. There is little variation by time period or continent. These have included studies on participant roles such as bystanders and onlookers. They also include studies of class factors such as injunctive norms (what behavior is commonly expected by other pupils within the class) and descriptive norms (the perception of what most pupils in the class actually do). Peer group dynamics are an important part of understanding any bullying behaviors, including cyberbullying, and are focused on explicitly in the KiVa anti-bullying program, which appears effective with cyberbullying as well as traditional bullying (Salmivalli, Kärna, & Poskiparta, 2011).

Teachers

Only 6% of articles included a focus on teachers. The role of teachers, both as a model of behaviour, and in terms of how they respond to incidents, has been shown to be an important factor in traditional bullying (e.g., Saarento et al., 2013). Their influence may however be somewhat less for cyberbullying. Firstly, much cyberbullying is at least initiated outside school.

Secondly, pupils seem rather less willing to seek help from teachers as regards cyberbullying, than parents and friends (e.g., Slonje & Smith, 2008). Interestingly there is a suggestion of a continent difference here, with Asian studies featuring teachers more often (10%) and North American and European studies less often (both 4%). This might possibly be aligned to greater respect for adults, including teachers (but also parents, see below) in Asian countries.

Parents

Compared to teachers, there were twice as many articles including some focus on parents (12%). Victims of cyberbullying more often confide in parents than teachers. In addition, some studies have focussed on the importance of parental supervision but not over-control (e.g., Sasson & Mesch, 2014) and of the general quality of parent-child relationships (e.g., Ang, 2015). Interestingly there is a suggestion of a continent difference, with Asian studies featuring parents more often (18%) and North American and European studies less often (10%, 11%). This again might possibly be aligned to greater respect for older adults in Asian countries.

Siblings

Very few studies (2%) had any focus on siblings. It has also been relatively neglected in traditional bullying, but a review by Wolke, Tippet, and Dantchev (2015) found 12 studies of sibling bullying. These showed it to have higher prevalence than peer bullying, and related to parenting quality and behavior. While cyberbullying might also occur between siblings, the few studies so far have mainly been on siblings as someone for victims to tell about their experiences or seek support. Its relevance for cyberbullying seems to be a potentially important but largely unexplored area.

Legal Issues

Very few studies (2%) had any focus on legal issues. Issues around what kinds of bullying behaviors are actually illegal are clearly important in traditional bullying; but there is special interest about such issues in cyberbullying, where the legal system in many countries is in catch-up mode as regards relatively new phenomena, and where case law is being established. These issues will also vary widely by country (Campbell & Završnik, 2013). This appears to be another rather neglected research area.

Coping Strategies

How victims of cyberbullying cope with the experience was a focus of 8% of articles. This has been slightly more of a focus in Europe (12%) than in North America or Asia (each 5%). Although a minority of victims say they are not much affected by cyberbullying and can ignore it, the kind of coping strategy adopted can impact on how severe the effects are (Machmutow, Perren, Sticca, & Alsaker, 2012).

Resources and Interventions

Some 9% of articles had a focus on resources for dealing with cyberbullying, or on interventions to reduce or prevent it. Clearly a fundamental aim of cyberbullying research should be to help design effective ways of reducing cyberbullying and the harm it causes. In a review of prevention and intervention strategies for adolescent cyberbullying, Ang (2015) discusses both general empathy training and modifying beliefs supportive of aggression, more

specific guidelines for Internet behavior, developing strong and positive parent-adolescent bonds, and training for teachers.

A review of thirteen intervention models using ICTs was provided by Nocentini, Zambuto, and Menesini (2015). They found only four of these had satisfactory evaluation. A number of promising interventions are under way or being developed (see e.g., chapters in Völlink, Dehue, & Mc Guckin, 2016; and special issue of *Aggressive Behavior*, 42(2), 2016), and hopefully substantive progress in this will come about in the next few years.

CONCLUSION

Our survey of journal articles on cyberbullying has provided a picture of the volume and content of research, this century. Some provisos should be noted, however. Our coverage was limited to one main search engine; however we found Web of Science to be comprehensive, and exploratory use of additional search engines did not greatly increase our database. We also had certain exclusion criteria. In particular we only covered English language publications. Also, we did not include books and book chapters (which typically do not have abstracts). While books and book chapters often synthesise research published elsewhere in journal format, they do sometimes provide original research findings not published elsewhere.

Cyberbullying has built on a previous research tradition in school bullying, but with inputs from other disciplines. We found there has been a decade of a rapidly increasing number of research studies, such that currently every week sees 2 or 3 new journal articles appearing. This has been a global phenomenon, with an initial impetus from North America but by now an even greater volume from Europe. By continent, only South America and Africa have so far lagged behind in this global development.

Cyberbullying has both similarities to and differences from traditional bullying. The types of cyberbullying are changing rapidly. There is still continuing debate about issues of measurement and definition, which the changing technological scene only exacerbates.

Many studies have reported prevalence rates, but these vary hugely; while important in making within-study comparisons, prevalence rates are less meaningful in absolute terms in the absence of consensus on definition and measurement across studies. The great majority of empirical studies have been quantitative, and cross-sectional. There is a need for more longitudinal studies, and also more qualitative and mixed methods approaches.

The most common focus of studies has been on risk factors and predictors of cyberbullying involvement, and on outcomes. There are many negative correlates of involvement; as much or maybe more than for traditional bullying. There has been considerable attention paid to the peer group, and also to parents; but much less to teachers, and also the role of siblings.

Legal issues around cyberbullying deserve more attention. There has been research on individual coping strategies, and also on resources, guidance and intervention. Theory-guided interventions are being developed, and it is important that these are fully evaluated so that further progress can be made in reducing cyberbullying and its negative effects.

Chapter 137

CONCEPTUAL AND DEFINITIONAL ISSUES REGARDING CYBERBULLYING: A CASE FOR USING THE TERM CYBER AGGRESSION?

INTRODUCTION

Recent literature has argued for a reconsideration of school-based traditional bullying and cyberbullying in terms of conceptualisation (e.g., Corcoran, Mc Guckin, & Prentice, 2015) and operationalisation (e.g., Corcoran & Mc Guckin, 2014). Corcoran et al. (2015) argue, within the context of cyber behaviour, for a move from cyberbullying toward the term “cyber aggression” due to complications with existing definitions and measurement tools. The present chapter critically appraises the current context of aggression from a definitional, typographical, and operational perspective. As a subset of aggression, bullying is discussed in the context of operationally defining traditional bullying. Furthermore, the methods and motives associated with this behaviour are considered. Definitions and issues with defining the behaviour are reviewed with regard to cyberbullying and a case is proposed as to the importance of behavioural measurement when assessing both traditional bullying and cyberbullying among children and young people (CYP). The chapter concludes with a discussion of a proposed move in the literature to a broader label of cyber aggression when discussing online abuse.

DEFINITIONS OF AGGRESSION

Anderson and Bushman (2002) define human aggression as “... any behaviour directed toward another individual that is carried out with the proximate (immediate) intent to cause

* Corresponding Author’s Email: paulinekcummins@gmail.com.

harm” (p. 28). It is further posited that the aggressor must prescribe to the notion that the act will cause harm to the target individual and that this individual will in turn strive to avoid the incident (Baron & Richardson, 1994; Berkowitz, 1993; Bushman & Anderson, 2001; Geen, 2001). The important consideration from this definition is the notion of “intention” within the context of the act. Accidental harm is not considered aggressive behaviour from this particular perspective as it lacks such intent (Anderson & Bushman, 2002). To further consider associated features of aggression and characteristics of aggressive acts, the “types” of aggression need to be acknowledged.

THEORIES OF AGGRESSION

From the biological perspective of aggression, two established accounts of aggression are offered by Lorenz (1974) and Krahé (2001). Emerging from the field of ethology, Lorenz (1974) proposed a model of aggression that stems from a genetic fighting instinct, where only the strongest males will acquire a mate and transfer their genetic material to subsequent generations, predicting the continuation of their lineage. This core philosophy concerns the continuous accumulation of aggressive energy in organisms manifesting in accordance with both individual and environmental factors, such as the amount of built up aggressive energy and the strength of the external stimuli that can activate an aggressive reaction (Lorenz, 1974). Lorenz (1974) would further argue that aggression is a pervasive and unavoidable feature of human nature. Sociobiology seeks to apply the logic of evolutionary theory to the understanding of social behaviour (Krahé, 2001), imbedded in Darwin’s (1859) *The Origin of Species*. From an evolutionary perspective, aggressive behaviour is adaptive, and exists to defend against attackers and rivals in the process of selection of mates (Archer, 1995; Buss & Shackelford, 1997; Daly & Wilson, 1994). Aggressive tendencies pass in accordance with the phylogeny of the species (Krahé, 2001), and have been used to explain sexual aggression in humans (Malamuth & Heilmann, 1998). The biological stance of human aggression being inevitable in human nature has been viewed as deterministic, and maintains that if an individual carries “the” aggressive gene, they will grow up to be violent. Behavioural geneticists disagree, however, arguing that genetic make-up may “predispose” a person to become an aggressive person, but environmental factors may intervene or reinforce it.

Due to Freud’s (1920) psychoanalytic account of aggression maintaining that aggressive behaviour was the expression of a genetically imbedded instinct, his theory initially was classified as a biological approach. Freud (1920) posited that human beings are wired for violence, inherent to all beings, which creates an urge to aggress against others. Freud (1920) argued that all human behaviour is driven by two key forces, (a) the death instinct (thanatos), and (b) the life instinct (eros). These can cause internal conflict which is only resolved when diverted away from the person onto other people. Consequently, an aggressive act towards other people is a mechanism for releasing the destructive energy to protect the individual and is termed as catharsis.

As a counterargument, drive theorists argue that aggression is an external drive to cause harm to others. This position is taken by several drive theories of aggression where external circumstances, especially that of frustration, provokes a motive to harm others (Berkowitz, 1989; Feshbach, 1984). A drive is not an always present force that increases in energy. Rather

it is only activated if an individual discovers that they are deprived of the means to fulfil an important need. The “frustration-aggression” hypothesis (Dollard, Doob, Miller, Mowrer, & Sears, 1939) argues that aggression is the result of a drive to end the feelings of frustration; an external interference in the goal-directed behaviour of the individual. Frustration leads to arousing the drive that concerns itself with harming other people or objects that are the source of the frustration. However, not every feeling of frustration results in aggression, rejecting sadness, depression, despair, and other emotive responses as possible outcomes (Krahé, 2001). Furthermore, people engage in aggressive acts as a response to many different factors, not just that of frustration. Berkowitz (1989, 1990, 1993) addressed these flaws with the cognitive neoassociation theory, postulating that the relationship between frustration and aggression is mediated by negative affect in the form of anger. Frustration would only result in aggression if the frustration evoked negative affect. Frustration not only elicits negative affect, but also aversive events such as provocations and loud noises. These experiences automatically evoke thoughts, memories, expressive motor reactions, and physiological responses that are associated with fight or flight responses. Stimuli present during a negative event become associated with the event in addition to the evoked cognitive and emotional responses. Aggressive thoughts, emotions, and behavioural tendencies become associated with the memory (Collins & Loftus, 1975). When concepts of similar meaning to these events are experienced, they trigger the same associations and feelings and in turn the same response. This can also be affected by metacognitive processes such as appraisal and reflection. Aggression is just one possible reaction to an aversive event or stimulus, and is not viewed as inevitable, but a feature of human behaviour which can be encouraged or suppressed by the emotional experience evoked by the negative event.

Many modern theories of aggression do not focus on one factor, rather they utilise knowledge from different areas of psychology to understand the factors that influence behaviour. Social Learning Theory (Bandura, 1997) is one such theory where it is argued that humans are not born with aggressive responses, but rather they are obtained like other forms of social behaviour through observational learning or direct experience. It is through social models, whether through direct experience or observational learning that social behaviours such as aggression are learned. Past experiences influence how one seeks to harm others, identifies appropriate victims for aggression, informs what actions are considered to justify retaliation or vengeance, and what settings are appropriate for aggression and where it is permitted (Baron, Branscombe, & Byrne, 2008). A more specific and detailed approach of Social Learning Theory, is Script Theory (Huesmann, 1986, 1998) which proposes that children learn aggressive scripts when they observe violent behaviour in the mass media. These scripts define situations and guide behaviour, with a person selecting a particular script for the given situation and taking on a prescribed role. This script can be retrieved at a later stage as a guide for behaviour once it has been learned. Scripts are sets of well-practiced, highly related concepts in memory, which can involve causal links, goals, and action plans (Abelson, 1981; Schank & Abelson, 1977). When these concepts become strongly related they become a script; a single concept in semantic memory. With more rehearsals of the script, this increases the number of activations of the script, and strengthens the links in the script. Within the context of social behaviour, when a child has witnessed several thousand occurrences of the use of a gun to resolve a dispute on television, they are likely to have developed a very acceptable script that has been generalised to many situations and is accessible for use. However, several studies have indicated that some people have a “hostile attribution bias,” whereby individuals who have a

history of aggressive behaviour prefer the interpretation of other people's behaviour as having hostile intentions, especially in the case of ambiguous behaviour (Geen, 1998). This bias can trigger an aggressive script and increase the likelihood for an aggressive response to be selected as the response.

Social Interaction Theory (Tedeschi & Felson, 1994) views aggressive behaviour as "social influence" behaviour. Here the actors use intimidating actions to create some change in the victim's behaviour. Coercive actions can be employed to gain something of value, to command justice for perceived wrong doings, or to gain desired social and self-identities. The actor is the decision maker, whose decisions are aimed at the anticipated rewards, costs and the likelihood of attaining different outcomes. In the context of aggression, this theory views aggressive behaviour as being motivated by higher level goals (Anderson & Bushman, 2002). For example, hostile aggression may have some rational objective behind it such as punishing the person provoking the response, in order to reduce the probability of future provocations. This theory refers to research that suggests that aggression is the consequence to threats to high self-esteem, especially to undeserved high self-esteem such as Narcissism (Baumeister, Smart, & Boden, 1996; Bushman & Baumeister, 1998).

The General Aggressive Model (Anderson, 1997; Anderson & Bushman, 2002) builds upon the Social Learning Theory, and is designed to integrate existing mini-theories of aggression into one theory. It argues that aggression is largely founded on the process of learning, activation, and application of aggression-associated schemas and scripts stored in memory. This theory maintains that a chain of events can result in overt aggression. It maintains that these cognitions can be started by two main types of input variables; personal factors and situational factors. Personal factors include traits that predispose some people for aggression, sex (males and females differ in aggressive tendencies), attitudes and beliefs about violence, traits, values, long-term goals, and scripts. Situation factors include frustration, provocation from another person, exposure to aggressive cues, anything that causes pain and discomfort, the use of drugs (alcohol and caffeine can increase aggression [Bushman, 1993]), and incentives. These personal and situational factors can lead to overt aggression through their influence on three routes; (a) arousal, (b) affect, and (c) cognition (Anderson & Bushman, 2002). For the first route of arousal, personal and situational factors can increase physiological arousal in a person. For the cognition route, they can induce hostile thoughts or bring attitudes and beliefs about aggression to mind, or through the use of scripts. Whereas with affect, they can arouse hostile feelings and these can be portrayed through expressive motor responses such as angry facial expressions. Depending on the individual's appraisal of the situation they can engage in thoughtful action which could result in restraining their anger, or they may engage in impulsive action, which can result in overt aggression. With repeated exposure to factors such as media violence and poor parenting among others, this can produce aggressive adults (Huesmann & Miller, 1994; Patterson, Reid, & Dishion, 1992). This long-term effect on personality is the result of the development, automatization and reinforcement of aggressive-related knowledge structures. The General Aggressive Model (Anderson & Bushman, 2002) suggests that long-term users of violent media can develop more aggressive stances, perceptual prejudices, attitudes, beliefs, and behaviours that are negative in nature, compared with what the person exhibited prior to the frequent exposure. The personal factors are clearly influenced with this repeated exposure, with changes in aggressive nature and tendency, but the long-term effects of exposure also impacts upon situational factors. In the case of the aggressive child,

the environment responds with the type of people that want to interact with this child, in addition to the types of interactions and situations available (Anderson & Bushman, 2002).

The Excitation Transfer Theory (Zillmann, 1983) maintains that physiological arousal tends to dissolve slowly over time, but elements of this arousal may remain in the person and transfer from one situation to the next. Thus if two arousing events are separated by a short period of time, the arousal from the first incident may be mis-assigned to the second event. If this second event evokes anger, then the extra arousal should lead to an increase in the person's anger level. The excitation is transferring from one event to the other, with the anger possibly extending over a longer period of time if the person has assigned the heightened arousal to this response. As a result, even when the arousal has reduced, the person is prepared to aggress for as long as the self-generated label of anger continues (Anderson & Bushman, 2002).

In conclusion, when discussing aggression, Berkowitz (1993) states that "... people have a capacity for aggression and violence, but not a biological urge to attack and destroy others that is continually building up inside of them" (p. 387). This is an argument that is supported by these aforementioned theories, emphasising the mediating role of cognitive, decision making, and learning processes. The following section will move focus from the theoretical to the practical, to the particular types of aggression which emerge across various contexts.

TYPES OF AGGRESSION

With regard to the typography of aggression, a number of forms exist. These include hostile, proactive, overt, relational, and instrumental aggression. Hostile aggression or reactive aggression can be defined as impulsive, unplanned, and motivated by anger, focused on harming the target, and as a response to perceived provocation; it is sometimes termed as affective or impulsive aggression (Anderson & Bushman, 2002). It is considered to be an impulsive, immediate response to a perceived threat, without any cognitive appraisal of the situation (Griffin & Gross, 2004). In contrast, proactive aggression is characterised by premeditated tactics of obtaining a particular goal other than harming the target (Anderson & Bushman, 2002), and tends to be unprovoked (Griffin & Gross, 2004). This form of aggression include two subtypes: (a) instrumental aggression (an attempt to claim an object such as a toy), and (b) bullying (aggression that is focused on domination or intimidation of a person). Overt or direct aggression is centred on confrontational behaviour towards others as observed in physical assaults, verbal threats, destruction of property, and self-injurious behaviour (Connor, Melloni, & Harrison, 1998). A further specific subtype of aggression is "relational" or "indirect" aggression which does not contain direct confrontation between the aggressor and the victim, but rather consists of behaviour such as exclusion, rejection from a peer group, rumour spreading, keeping secrets, and embarrassment in a social context (Griffin & Gross, 2004). Therefore, it is important to consider these types of aggression when considering bullying behaviour as it can be located in a number of these types of aggression such as relational and reactive as it can be verbal, physical, social, and cyber based (Law, Shapka, Hymel, Olson, & Waterhouse, 2012). Consequently, bullying can also be considered a specific aggressive behaviour, a theme that will be discussed in the subsequent section.

BULLYING

As aggression is concerned with the intention to cause harm or upset to another person, bullying behaviour can be closely linked to aggression, and can be considered a subcategory of it. Primarily a behaviour that is unidirectional, bullying exists where one person repeatedly assaults one or more people who do not have power, or have very little power, to react (Olweus, 1993). Similarly, Stephenson and Smith (1989) suggest that the prerequisite for an incident to be considered bullying is with the presence of an aggressive act, which in turn causes upset to the victim. Bullying can therefore be viewed as an extension of aggressive behaviour. Where bullying differs from aggression lies in the frequency of the behaviour, as aggression can be one single act and short-term, whereas bullying generally requires an element of repetition in the behaviour and over time (Krahé, 2001). Similar to aggression, bullying can take different forms, and thus can be located within the various forms of aggression. The next section will address the issues with defining this behaviour.

OPERATIONALLY DEFINING BULLYING

To measure something consistently requires a clear operationally defined construct. However, there is not one distinct agreed definition of bullying within the area of bullying research. Previously, there was disagreement within the literature on the key characteristics of this behaviour and, especially so, cross-culturally. One of the first descriptions of the behaviour was by Heinemann (1973) in the use of the Norwegian term “mobbing,” to describe when group violence is enacted on a deviant person and is started and finished suddenly. This is defined as a group behaviour against an individual, similar to the term “mobbing” used in the English language. A similar term also was used in the German literature (Niedl, 1996). However, these descriptions do not account for bullying at the individual level of one person bullying another.

The term bullying is well established in the English language, and can be traced in literature back to the novel *Tom Brown's Schooldays* (Hughes, 1857/1989). Within the research literature, Olweus (1978) provided the foundation publication in the area, where he employed a similar definition to that of Heinemann (1973). However, Olweus (1999) did not initially acknowledge the role of indirect bullying in his earlier definitions and it did not include the systematic one-to-one attacks of a stronger child against a weaker child. He has since adapted his definition in later years to include these characteristics (Olweus, 1999). This systematic abuse of power seen in bullying behaviour is a feature widely used within the literature and adopted by theorists (Rigby, 2002).

Later definitions have agreed upon three main criteria for bullying behaviour; repetition of the behaviour, a power imbalance between the aggressor and the victim, and intention to cause harm (Olweus, 1993, 1997, 1999; O'Moore & Minton, 2004; Rigby, 2002). The feature of a “repetitious act” is one that O'Moore and Minton (2004) suggest should be an exception when classifying an incident as bullying, as they view that one particular serious occurrence of the behaviour can lead to a continued feeling of intimidation, an exception that Olweus (1999) concurs with. Furthermore, it can be added that bullying behaviour can occur without provocation (Olweus, 1994) and the act can be physical contact, words, or other actions such

as gestures, facial expressions, or exclusion. These characteristics tend to be the agreed terms when identifying bullying generally within the literature (Farrington, 1993; Smith & Sharp, 1994).

In a cross-cultural comparison (England, Italy, Japan, Portugal, and Spain) of the definition of and conceptualisation of bullying, Smorti, Menesini, and Smith (2003) noted that when the English term “bullying” was translated into other languages, there was no such word that captured the exact meaning that exists in the English form of the word. This is particularly the case in Latin languages such as French, where there is no direct translation for the English word “bullying” (Smith, Cowie, Olafsson, & Liefvooghe, 2002). In some other cultures, other terms are used to describe the behaviour. For example, in Japan bullying is described as “ijime” that is bullying within the same year group as a methodical social exclusion. In South Korea bullying has been labelled as “wang-ta” where it involves social exclusion by all classmates, and “jun-ta”, where it involves social exclusion by the whole school (Kwak & Koo, 2004). In Italy, “prepotenza” and “violenza” are employed but tend to describe acts that are physical and violent (Fonzi et al., 1999). Due to this variation in terms when describing bullying behaviour, it is important that the focus is on the characteristics rather than on the term to successfully identify the behaviour. Having discussed the issues of defining the behaviour, the next section will provide details on the methods and motives of bullying behaviour.

METHODS AND MOTIVATIONS OF BULLYING

Face-to-face, or traditional bullying, can be conducted using a number of methods, such as physical, verbal, or relational, and can be carried out by the same bully on the same victim (Benbenishty & Astor, 2005; Nishina, 2004; Rigby, 2002). Physical bullying is the most obvious form and recognised by all with features of kicking, hitting, and beating among others (Smith et al., 2002). As children mature, verbal bullying becomes more common than physical bullying, consisting of repeated derogatory remarks or names (Berger, 2007). Both of these forms of bullying can also be labelled as direct forms of bullying (Griffin & Gross, 2004). Relational or indirect bullying is characterised by exclusion, social rejection, ignoring, and spreading rumours (Griffin & Gross, 2004), where there is a disruption to the social relationship (Berger, 2007). This type of bullying is more common and more hurtful in puberty when children are more socially skilled and when peer approval is central (Underwood, 2003; Xie, Swift, Cairns, & Cairns, 2002). These forms of bullying have also been associated with proactive and reactive aggression (Pellegrini, Bartini, & Brooks, 1999).

Bullying has now moved outside of the traditional methods of bullying, to occur in the online environment and has been labelled as cyberbullying. When defining face-to-face bullying, the characteristics do not refer to cyberbullying. However, it may be viewed as similar to traditional bullying but occurring through the use of new communication technologies (Menesini & Nocentini, 2009), through social networking sites, instant messaging services, chat rooms, and chat features of games, among others.

The characteristics also do not make mention of the motivations such as homophobic bullying, racist bullying, and disabilist bullying among others. However, in accounting for these forms of bullying, they can be seen as an extension of traditional bullying. In these cases, the bully can be said to be motivated by a characteristic of the person such as disability, gender,

disfigurement, race, ethnicity, skin colour, sexual orientation, religious belief, gender identity, community, or status in terms of being an asylum seeker or refugee. This can also be referred to as identity-based bullying (Tippett, Houlston, & Smith, 2010). Therefore, researchers and schools need to be aware of both the motives and methods when designing intervention and prevention anti-bullying programmes.

DEFINING CYBERBULLYING

Recent years have seen the expansion of the Internet and social interactions in the online environment with the fast development of information and communication technology (ICT). Ownership of mobile phones and Smartphones has increased exponentially with upwards of 7.4 billion mobile phones estimated in the world, 3.4 billion of these being Smartphones, with the number of mobile phones owned expected to exceed 9 billion by 2021 (Ericsson, 2015). Coupled with this is the increased use of social networking sites, apps, chat room, and other media to communicate. Communication through previously considered non-typical means is now popular and ICT has become engrained in our communication with one another. Expansion in technology and communication provides great advantages, but some consequences of these advancements are problems such as bullying, trolling, and stalking.

From the online perspective, bullying is termed as “cyberbullying”, an umbrella term for a selection of similar concepts, such as online bullying, Internet harassment, online aggression, and electronic aggression (Dooley, Pyżalski, & Cross, 2009; Kowalski, Limber, & Agatston, 2008; Smith, 2009; Tokunaga, 2010). It has been viewed as similar to traditional bullying, but it has a unique venue (Dooley et al., 2009), with the use of electronic forms of contact (Sticca & Perren, 2013). However, defining the concept has been difficult. The term cyber is guilty of the same problem as bullying when defining the construct. Cyber conjures up different connotations in different languages. In the German dictionary, “cyber” speaks of an online computer contrived environment that is treated by the individual as an extension of reality (Nocentini et al., 2010). In Italy it is the use of electronic means and virtual environment (Garzanti, 2007), whereas in Spain, “ciber” makes reference to computer networks (RAE, 2016). Consequently, the term denotes different meaning across languages and countries which poses a problem when operationally defining the construct. As a result, there are a number of different definitions that describe cyberbullying, many of which are derived from the traditional bullying domain. Due to these differing definitions, there is no uniform, agreed definition of the behaviour. Ybarra and Mitchell (2004) defined cyberbullying as an explicit, deliberate act of aggression, online, towards another person. Juvonen and Gross (2008) define it as insulting or threatening someone through the use of the Internet or other digital communications. One definition that closely resembles Olweus’s definition of traditional bullying, is offered by Smith et al. (2008), where they define cyberbullying as “... an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself” (p. 376). This definition has similar characteristics to traditional bullying; intention to cause harm through an aggressive act, imbalance of power, and repetition of victimisation (Grigg, 2010), but with the addition of technological devices to commit the act (Dooley et al., 2009; Slonje & Smith, 2008; Smith et al., 2008).

The imbalance of power that occurs online can refer to the victim's lack of power, instead of the perpetrator's possession of power (Dooley et al., 2009). This may also be due to the aggressor's real life power of strength or age over the victim, where the victim knows the perpetrator possibly from being bullied through traditional means. Thus the determinants of traditional bullying could be also be factors for cyberbullying (Slonje & Smith, 2008), so the real life physical imbalance may play a role in the online setting. Or, this imbalance can be attributed to a victim's perspective of the perpetrator as being a digital expert (Vandebosch & Van Cleemput, 2008) and cannot defend themselves from the actions of the perpetrator.

This use of electronic means as the medium of contact entails some differences to traditional bullying. Cyber communication allows for a potentially larger audience to witness bullying (Kowalski et al., 2008), the increased possibility of anonymity for the aggressor, a decrease in the amount of direct feedback between the bully and victim, along with decreased time and space limits (Slonje & Smith, 2008), and supervision (Patchin & Hinduja, 2006). With regard to the repetitious nature of the behaviour, in the case of cyberbullying even a single act can be disseminated widely, copied by others, and reposted, thus meeting the criteria, and repeatedly creating that imbalance of power (Menesini & Nocentini, 2009). Furthermore, due to the archival nature of the Internet, it is possible for victims and bullies to re-read, re-look at the event, and re-experience it (Law et al., 2012). In addition, where offline bullying occurs in real-time, online bullying is not limited by time (Walther, 2007) and it can occur at anytime and anywhere. With traditional bullying, once the victim gets home they can avoid the bullying until the next day, whereas victims of cyberbullying may still receive messages, comments, or emails wherever they are (Slonje & Smith, 2008).

As the perpetrator and the victim are communicating online, there is no way for the perpetrator to see the impact of their action on the victim (Smith, 2012) and this may result in disinhibition and deindividualisation (Agatston, Kowalski, & Limber, 2012; Davis & Nixon, 2012; Patchin & Hinduja, 2011; von Marées & Petermann, 2012). This emotional disconnect can sever any empathetic responses that might have emerged in a face-to-face situation (Cassidy, Faucher, & Jackson, 2013). However, this medium of bullying may not appeal to bullies who like the feedback that they receive in a face-to-face bullying situation as they do not have the opportunity to demonstrate their power over the victim or to see their reactions (Smith & Slonje, 2010). For some cyberbullies however, it is suggested that they enjoy the anticipation of the response or impact of their actions at a later stage (Nathan, 2009).

Bullying behaviour has evolved from using mobile phone for bullying through text messages and phone calls to now include picture/video clip bullying and happy-slapping – where the victim is slapped or made to look silly and it is filmed and the content circulated to others (Smith et al., 2008). Similarly, using the Internet for bullying is no longer confined to just emails. It now includes bullying in chat rooms, instant messaging, and websites – forums and social networking sites (Smith et al., 2008). With the advancements of ICT it is envisaged that this behaviour will continue to evolve using the new media.

Olweus (2012) holds that cyberbullying should not be examined separately from traditional bullying, but rather they should be understood in conjunction with one another. Furthermore, and despite media claims to the contrary, he holds that there has been no increase in the prevalence of cyberbullying over time, nor has there been an increase in the number of victims. Rather it is a behaviour overrated by media, with a low incidence rate, and where there are not many new victims or bullies. Olweus (2012) argues that there is an overlap between traditional bullying and cyberbullying. As a consequence, it is suggested that schools should focus on

policies to deal with traditional bullying and include system-level strategies to tackle cyberbullying problems. In response to this, Smith (2012) challenges this stance, and disputes the claim that cyberbullying has a low rate of occurrence, and contends that Olweus (2012) underestimates the role of cyberbullying especially in research programmes. He indicates that cyberbullying in fact is on the increase, providing research evidence of this over a five-year period, and furthermore states that in some countries, traditional bullying has decreased in prevalence over the past 10-20 years (Rigby & Smith, 2011). Furthermore, as the use of the online environment expands, so too do the opportunities to target individuals to abuse, providing a greater number of possible targets.

Following this, Smith (2012) discussed key differences between cyberbullying and traditional bullying. These distinctions include: (a) the requirement for technological expertise when cyberbullying, (b) the role of anonymity, (c) the possibility that the perpetrator does not witness the victim's response, (d) the role of the bystander (who may be present with the victim, with the bully, or with neither when the victimization occurs), (e) the greater potential audience in the online setting, and (f) the difficulty for the victim to escape cyberbullying. In addition to this, Smith (2012) discusses the issues of repetition and power imbalance. His own definition is an adaption of the definition for traditional bullying by Olweus (2012), with the features of aggression, intention, repetition, and power imbalance. However, Smith (2012) notes that just one post online by a perpetrator can constitute a repetitious act, as it can be reposted by others although this act is not by the perpetrator. The physical power imbalance is not present in the online setting and, therefore, Smith (2012) suggests rethinking this. However, this imbalance may be present in a non-physical manner. Smith (2012) concludes that although Olweus (2012) makes some valid points, he underestimates the differences and role of cyberbullying within research.

With regard to the overlapping nature of face-to-face bullying and cyberbullying, Patchin and Hinduja (2006) highlight how bullying is "moving beyond the schoolyard" thus highlighting that victims of cyberbullying are also targets of traditional bullying; a finding that Ybarra, Diener-West, and Leaf (2007) report on, with 36% of children in their sample experiencing traditional and cyberbullying concurrently. Juvonen and Gross (2008) similarly report on this, with 85% of their cyber victims experiencing victimisation in school also. In these cases, it can be the same or different people committing the aggressive acts (Ybarra et al., 2007). When this is the same person, the bully is using cyberbullying in combination with traditional bullying to maximise the harm that they can inflict on the victim (Tokunaga, 2010). This overlapping nature of the behaviour has been reported in research with a consistent correlation between involvement in cyberbullying and traditional bullying (Didden et al., 2009; Juvonen & Gross, 2008; Katzer, Fetchenhauer, & Belschak, 2009; Slonje & Smith, 2008; Smith et al., 2008). However, when considering these behaviours, the issues with defining the constructs also extends to measurement of traditional bullying and cyberbullying.

ISSUES WHEN MEASURING BULLYING

When comparing research findings an issue emerges in terms of incidence rates. Due to the lack of agreement on the definition for identifying bullying behaviour, this problem extends to

measuring the behaviour. Solberg and Olweus (2003) highlighted issues surrounding the measurement of traditional bullying. In terms of the sources of data, different sources of measurement have been employed; those of normative and ipsative; normative being the reporting of bullying from the stance of a teacher or peer, and ipsative being the self-reporting of victimisation. In addition, in some cases a definition of bullying is presented to the participant prior to completing the questionnaire. Where there is no definition, there is room for subjectivity by the participant for their interpretation of the behaviour.

The next issue Solberg and Olweus (2003) discussed is the time reference period employed across research studies, which involves ranges which vary from a year, to the past term, to the past two or three months, or indeed in some cases no indication of time frame at all. The response options presented to participants also vary across research studies, with some including a dichotomous response of “yes-no,” some with a range of categories such as “does not apply at all” to “very often,” and in other cases a frequency-based response of “seldom” to “very often” or a more specific frequency based response of “not at all in the past couple of months” to “several times a week.” How research studies report on the prevalence rates also differs where some calculate incidence rates based on a single item or key global questions and other studies employ a series of questions added or averaged together to assess the construct (Solberg & Olweus, 2003). These issues should be noted when trying to compare incidence rates from study to study. Although these differences were noted in relation to traditional bullying, cyberbullying also suffers from the same issues of measurement and reporting (Menesini & Nocentini, 2009), as much research in the area has employed self-report measures with key global questions, whereas other research focused on types of behaviours. These measurement issues and problems with definitions have also been outlined by Mc Guckin, Cummins, and Lewis (2010), indicating that such inconsistencies in the research area make comparisons between studies difficult. Menesini and Nocentini (2009) suggest that a more accurate approach to measure bullying behaviour is through a multiple-item scale instead of a global question. Nunnally (1978) argues that these multiple-item scales carry more validity than a single-item measure which cannot fully represent a complex construct and cannot distinguish between the finer details of the concept. Thus the multiple-item scale can assess these finer details, to provide a more accurate and precise assessment of the concept with more reliability. Considering methodological issues of measurement concerning bullying behaviour, and the difficulty with operationally defining cyberbullying under the original three key criteria of face-to-face bullying, the focus should be on the behaviours associated with bullying rather than global questions.

CYBERBULLYING OR CYBER AGGRESSION?

Tokunaga (2010) offers an alternative definition to Smith et al. (2008) based on a meta-synthesis of the term; proposing that it is “... any behaviour performed through electronic or digital media by individuals or groups that repeatedly communicates hostile or aggressive messages intended to inflict harm or discomfort on others” (p. 278). However, this definition has been developed based on previous definitions in the literature. These previous definitions contain limitations and are not consistent across languages and countries. In comparison, Langos (2012) postulates that cyberbullying is underpinned by the elements of traditional

bullying, those of aggression, power imbalance, intention, and repetition but it consists of direct and indirect forms of the behaviour where the former is based on a private interaction such as in the case of a text message, and the latter is a public interaction such as on social networking sites. Both forms of the behaviour features the power imbalance, where the victim cannot defend themselves against the intent to cause harm to them. She expands to say that the repetitious nature of cyberbullying is more visible in the direct form of the behaviour, as it is direct action by the perpetrator, whereas it is more difficult in the case of indirect cyberbullying. This direct action also demonstrates the intent of the perpetrator to cause harm to the victim, which is not as clearly visible in indirect cyberbullying. Thus the indirect form, may be a single act or multiple acts by the perpetrator towards the victim. With regard to this intention to harm the victim, Langos (2012) postulates that one should assume the viewpoint of the victim, and whether a reasonable individual would consider the act(s) as intentionally harmful to the victim.

With the problems surrounding operationally defining the concept, Grigg (2010) offers an unconventional solution in comparison to other researchers in the area. She proposes that researchers should move away from the label of cyberbullying and move towards cyber aggression, a concept that considers aggression more broadly in the cyber setting. With regard to the imbalance of power element of cyberbullying, Grigg (2010) argues that there is no empirical research supporting the stance that perpetrators of cyberbullying are media experts. Furthermore, the responsibility for the repetitious element is unclear in terms of whether this falls to the perpetrator or the bystander in the context of repeated viewing of the negative act. The role of the bully is clear in the case where the negative act is repeated, but in the case of repeated viewing of content or forwarding of the content, the one-time action of the bully may be viewed by bystanders or shared and “passed along”, reinforcing the negative act rather than supporting the victim or ignoring it. Grigg (2010) proposes a definition of cyber aggression which is considered “... intentional harm delivered by the use of electronic means to a person or a group of people irrespective of their age, who perceive(s) such acts as offensive, derogatory, harmful or unwanted” (p. 152). She concludes that this definition of cyber aggression considers behaviours such as bullying, harassment, stalking, abuse, assault, or hostility, along with “happy slapping,” “outing,” and “flaming,” where all of these behaviours employ smart phones or the Internet to conduct the behaviour. The description omits the elements of power imbalance and the repetition that is a feature in definitions of cyberbullying, however, the role of the bystander should be considered in the understanding of cyber aggression.

Corcoran et al. (2015) support this stance by Grigg (2010), where they posit that there should be a move towards cyber aggression, rather than an attempt to try and “fit” the unsuitable criteria into a definition of cyberbullying. They draw on this research by Grigg (2010) and Langos (2012), and also by Pyżalski (2012), stressing that research should consider the target individual(s) in cyberbullying. It should be examined whether the behaviour was peer-directed cyber aggression, at individual(s) within the peer group, or electronic aggression, focused on individual(s) outside of the peer group such as random victims, celebrities, school staff, groups, and vulnerable individuals. Corcoran et al. (2015) propose a definition of cyber aggression as “... any behaviour enacted through the use of information and communication technologies that is intended to harm another person(s) that the target person(s) wants to avoid. Intent to cause harm should be judged on the basis of how a reasonable person would assess intent” (pp. 252-253).

This proposed definition allows for a deviation from the restrictions of a definition based on traditional bullying, and considers the aforementioned issues highlighted by Grigg (2010), Langos (2012), and Pyżalski (2012). This cyber aggression definition is developed based on five conclusions by Corcoran et al. (2015) regarding issues with using the term cyberbullying. Firstly, the term cyberbullying suggests that it is an extension of traditional bullying, using the same criteria for the behaviour except in the location of cyberspace. This creates a difficulty in that, as pointed out by previous researchers, it is difficult to identify these features in cyberspace due to the nature of the online environment. Secondly, with respect to the features of cyberbullying, there is a disagreement within the literature as to the exact features of the behaviour, thus providing difficulty with operationally defining the construct (Menesini et al., 2013; Nocentini et al., 2010; Vandebosch & Van Cleemput, 2008). Thirdly, concerning the interaction between the victim and aggressor, bullying is considered a form of social aggression (Björkqvist, Ekman, & Lagerspetz, 1982), and by definition this would exclude any incidents of cyberbullying where the aggressor is unknown by the victim, such as in the case of “happy slapping.” Therefore, considering the concept in terms of social aggression would mean an oversight in omitting behaviours that would otherwise be considered a form of cyberbullying. Consequently, there is a need for a more inclusive concept such as cyber-aggression. Fourthly, research by Corcoran and Mc Guckin (2014) demonstrated the difference between researchers' understanding of the behaviour and the associated label, and students' understanding of cyberbullying. This highlights a disconnect between the understanding in research of cyberbullying and what those involved perceive the behaviour to be. This could be attributed to a lack of awareness of the construct on the part of those involved and a need to educate students on the behaviour. It also, however, may be an issue with defining the construct and a need to use a different term such as cyber aggression. Corcoran and Mc Guckin (2014) employed a multiple-item scale approach to measuring cyber aggression, coupled with a global question to assess the construct of cyberbullying. The scale measure provided an overview of the incidence of cyber aggression under elements considered to be associated with bullying behaviour, and yielded a higher rate of involvement compared to the global question. This may provide a more holistic picture of what was happening on the ground for those involved. Corcoran et al. (2015) conclude that this supporting research suggests at this point that the term cyberbullying is unclear and outdated. Fifthly, the lower incidence rate reported by Corcoran and Mc Guckin (2014) could be attributed to the stigmatisation of reporting the behaviour. This supports the requirement for another approach to provide a better assessment of the behaviour. This may well be offered by the term cyber aggression.

CONCLUSION

This definition of cyber aggression offered by Corcoran et al. (2015) provides a holistic approach to assessing this behaviour in a more inclusive manner. Grigg (2010) described the “vagueness, restrictiveness and ambiguity” (p.152) associated with using the term cyberbullying and describes cyber aggression as an approach that considered broad negative behaviours that occur online. Considering that bullying behaviour as a whole can be viewed as a subcategory of aggression, a term of cyber aggression is more fitting when describing this online behaviour. This provides clarity when dealing with the behaviour, removing the

constraints with the criteria previously set by definitions of traditional behaviour. Furthermore, as a sub-category of aggression, the theories of aggression, whether biological or psychological, highlight the argument of the inherent possibility of aggression in humans. It is only through the mediating roles of cognitive, decision making, and learning processes the aggression can be reduced or prevented. Consequently, this stance of viewing online bullying as a form of cyber aggression provides a more precise account of the behaviour. Furthermore, in doing so, research should consider employing multiple-item scales that offer more reliable and valid measures of the behaviour rather than a number of global based items.

Chapter 138

PREVALENCE RATES OF CYBERBULLYING FROM A CROSS-NATIONAL PERSPECTIVE: DEFINITIONAL AND METHODOLOGICAL ISSUES

Irene Connolly*, PhD

Dun Laoghaire Institute of Art, Design & Technology (IADT), Dublin, Ireland

INTRODUCTION

Cross-cultural cyberbullying research, while extensive, is varied in relation to prevalence rates. Many reasons have been put forward regarding these issues, with the focus pointing towards definition of concepts and methodologies used. Society's rapid technological development also causes problems, with earlier research focusing on mobile phones and Internet based behaviour independently. However, with the ability to access the Internet from smartphones, and the increasing uptake of smartphones by young people, it is now almost impossible to view these devices as separate entities (Genta et al., 2012). Smartphones are perceived among children and adolescents as "extensions" of their body (Mascheroni & Ólafsson, 2014), that can be easily kept in a pocket (Stald, 2008) and aids a feeling of permanent contact with friends and family. This chapter will explore the reasons behind the varying levels of cyberbullying, cross-nationally. This chapter begins by exploring with the variety of definitions used in the research, and then focuses on the various methodologies employed by researchers which are intertwined with the cultural context of the research.

FACTORS INFLUENCING THE DEVELOPMENT OF A CYBERBULLYING DEFINITION

The act of bullying is multi-dimensional and can be categorised as: *overt/covert, direct/indirect, physical/verbal, social/relational*, and having *psychological/physical impact*.

* Corresponding Author's Email: Irene.Connolly@iadt.ie.

Experts in the area of cyberbullying tend to vary in their use of a standard definition, mainly as a result of previous research carried out, the cultural context in which the research is being conducted, and the aspect or component of cyberbullying being examined. Many researchers distinguish bullying from other aggressive behaviour due to deliberate intent to harm, power imbalance, and repeated behaviour (Olweus, 1993). One of the most widely used definitions of cyberbullying is Smith et al.,’s (2008) “... an aggressive intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself” (p. 376), which is a direct modification of Olweus’ (1989) definition of traditional bullying. However, in addition to this definition is the emergence of new criteria essential for a definition of cyberbullying which include; anonymity, 24/7 or unlimited access, and exposure to large audience (Menesini & Nocentini, 2009; Slonje & Smith, 2008; Tokunaga, 2010), which are not entertained in the aforementioned definition. Further examination of the definition has led researchers (Corcoran, Mc Guckin, & Prentice, 2015) to suggest that cyberbullying itself is too narrow of a concept when applying the issue of bullying to the cyber world, and that the bullying behaviour that occurs in the online world is more suggestive of cyber-aggression. Adapting the definition of traditional bullying to encompass the myriad of behaviours associated with cyberbullying may not be the best fit or approach. There are several aspects of cyberbullying that are completely distinct to those of traditional bullying.

In an examination of concepts of repetition, power imbalance and intention to harm in the development of a definition of cyberbullying, there is a large variation with regards to how these are applicable to the traditional form of bullying. Researchers have found that they play a big role in the development of a definition of cyberbullying. *Repetition* is resolutely recognized as being a key criterion in cyberbullying (Patchin & Hinduja, 2006). It is an imperative principle to allow for distinction between a joke or jovial teasing and an intentional attack (Nocentini et al., 2010) and establishes systematic behaviour. The online world alters the understanding of repetition in relation to cyberbullying occurrences. The indefinite nature of cyberspace means that messages can be shared or forwarded to others, and photos can exist for an undetermined length of time (Slonje & Smith, 2008). Direct cyberbullying occurs when communications, whether by Instant Messaging (IM), text, multimedia messaging or e-mail is sent directly to the cyber-victim with the intention of having an immediate effect on them. This direct cyberbullying does not involve the use of public cyberspace, just private interaction. Within the direct cyberbullying context, repetition occurs as a consequence of several contacts, this would be more similar to the repetitious nature of traditional bullying. Whereas indirect cyberbullying, in the public arena can be established simply by its appearance in that forum (Brenner & Rehberg, 2009). In this sense, a single photo that is uploaded and shared or liked by others can gain a huge audience. In cyberbullying, some acts may occur just once, such as a photo or video being uploaded by the primary perpetrator and therefore may not fit into the concept of repetition. These acts may include *outing*, *happy slapping*, *flaming*, and *sexting* (Dooley, Pyzalski, & Cross, 2009; Spears, Slee, Owens, & Johnson, 2009). However, repetition is evidenced due to the amount of times that the video/photo/text is viewed by different recipients or passed along by various bystanders, the term *going viral* is a concept we have become familiar with, as material moves easily across the world via the Internet (Smith et al., 2008; Vandebosch & Van Cleemput, 2008). Within this context, distasteful pictures and video clips are identified as particularly disturbing, due to the extent of the audience who view these contents and the subsequent psychological effect that these may pose to the targets (Gillespie,

2006; Smith et al., 2008). Traditional classifications would assign this repetition to the perpetrator but in the cyber context this is more multifaceted where the repetition can be attributed to either the primary perpetrator or the bystanders. Cyber-bystanders can strengthen the harassment by forwarding on the information (Smith et al., 2008). Furthermore, Grigg (2010) discusses a lack of transparency, in whether the accountability lies with the cyberbully or the bystanders when repetition occurs, in the form of repeated views of degrading material. Within the concept of cyberbullying, this is considered repetition but does this really fit the idea of repetition in the traditional sense? The role of repetition in the definition of cyberbullying is controversial, the complexity of the nature of repetition in cyberbullying in private and public forums adds to this controversy. Many researchers see it as an essential element within a definition of cyberbullying, while others feel that the element of repetition is not always present, and therefore irrelevant and hence not included in their definition. In addition to repetition, further controversial aspects in the development of a cyberbullying definition are the *imbalance of power* and *anonymity*.

The *imbalance of power* in cyberbullying exists due to the fact that a cyberbully can penetrate the home environment of a cyber-victim, accessing their private time 24/7 or indefinitely. Just as there are no limitations for the cyber-bully, there is little escape for the cyber-victim. While many would argue that the removal of the technology by the parents or withdrawal by the young person themselves will rectify this imbalance, it will only do so for a short time. Young peoples' social and emotional development is intrinsically linked to social media. It is simply an extension of their socialisation. Social media is all encompassing and an absolute communicative necessity, in the eyes of young people. For most it would be difficult to imagine a life without it. Trying to separate the young person, from the technology, will never result in a long term solution to the problem. Within, the power imbalance aspect of cyberbullying, a cyber-bully obtains the upper hand and may make the cyber-victim feel helpless (Dooley et al., 2009). In an attempt to counter this helplessness, many try to protect themselves using technical interventions such as blocking, changing passwords or emails and usernames or deleting anonymous texts without reading them (Aricak et al, 2008; Smith et al, 2008). Moreover, the size of the potential cyber audience may cause an imbalance of power for the cyber-victim also, experiencing an inability to defend themselves. In cyberspace, a cyber-bully is presented with new incidents in which to exhibit their power over an apparent weaker victim. It has been suggested that varying degrees of technological skill may create a power differential between a cyber-bully and a victim in the digital world (Vandabosch & Cleemput, 2008). However, in a society where toddlers are now accessing tablets, to watch their favourite animated shows and to play games, this divide is not as prominent today as it was a few years ago. In fact, this technological prowess should be used in the prevention of cyberbullying, including savvy use of privacy settings to re-establish equilibrium in the online world for the target.

A further power discrepancy exists in relation to the existence of *anonymity* in the online world. It may be the anonymity that encourages a cyberbully to behave in this maladaptive way. The feelings of helplessness experienced by the cyber-victim may be increased as a result of not knowing the identity of those behind the cyberbullying (Vandabosch & Cleemput, 2008). It can be difficult to respond when the person causing the torment remains unknown, therefore the victim could be interpreted as the weaker party. Research has shown that 40%–50% of those who are victimized by cyberbullies know the identity of the perpetrator (Kowalski & Limber, 2007; Wolak, Mitchell, & Finkelhor, 2007), which indicates that many cyber-victims are

unaware of the perpetrator's identity. This leads to further psychological torment for the cyber-victim. The area of anonymity is a problematic one, some argue that the removal of anonymity online would affect one's civil rights. However, in the online world, the effect of disinhibition combined with anonymity appears to alter people's behaviour. An almost dual Bruce Banner/the Hulk personality existing, while operating face to face, individuals are temperate and polite, yet in the online world some individuals release a torrent of abuse on others. Whether it is famous people, online bloggers, or just ordinary people, few can escape the wrath of these individuals. While anonymity provides a safe hiding place for the perpetrator, it simultaneously disallows the target any protection. It could be argued that expression of one's thoughts in social media should be accompanied by identifying facts, such as photos and location. This view would assert that if you are not afraid of sharing your views online, then you should not mind having the world being able to identify you. Individual governments' intervention would motivate social networking companies to adhere to a non-anonymous online environment. It would be interesting to see the impact that this would have.

Two further aspects in the development of a definition of cyberbullying are the roles of *intention* and *aggression*. While mentioned in the definition by Smith et al., (2008) these concepts are omitted from some definitions. Intention and aggression are intrinsically linked within the area of bullying. The elements that build the definition of aggression are the same as bullying (Smith et al., 2002), where bullying, stalking and aggression are repeated forms of aggression (Dooley et al., 2009). Grigg (2010) emphasizes the need to consider different perspectives on cyber-based aggression in the development of a definition of cyberbullying. She defined "cyber aggression" as "... intentional harm delivered by the use of electronic means to a person or a group of people irrespective of their age, who perceive(s) such acts as offensive, derogatory, harmful, or unwanted" (p. 152). This argument, that there is a need to look at aggression more broadly, is highlighted by Corcoran et al., (2015). Bullying emerges as a subset of aggression due to the presence of repetition and power imbalance (Monks & Smith, 2006). Arguments for and against the inclusion of intention in a definition of bullying relate to the arguments advanced in the context of aggression (Baron, 1977; Geen, 2001; Guerin & Hennessy, 2002). Without its inclusion, joking, jovial teasing, and unintentional behaviours are depicted in an excessively wide-ranging meaning of bullying. In the same way, inadvertent online behaviours and behaviours such as good-natured cyber-teasing and cyber-joking, which do not involve the essentials of repetition, power imbalance, or intention to cause harm to someone, would be branded belligerent cyber acts.

An examination of definitions cross-culturally have been conducted in relation to the varying use of concepts within definitions (Menesini et al., 2012; Smith, 2012). It was Olweus (2012) who emphasised the importance of a definition for standardisation of prevalence rates cross-culturally and nationally (Palfrey, 2008). As a starting point in research, a standardised definition could lead to more standardised methodologies and hence more transparent prevalence rates. In addition, a systematic literature review by Smith (2012) of 44 studies, focused on instruments developed for cyberbullying assessment and the definitions used in these studies. Smith (2012) reported that the majority of the definitions stress the fact that cyberbullying behaviour occurs through electronic devices/media (42 of the 44). Furthermore, 40 of the 44 definitions included the condition that the cyberbully must have the intention to harm.

Repetition of the behaviour occurred less, where only 25 of the 44 studies included it, and imbalance of power was presented in only 13 of the 44 definitions. Smith (2012) concluded

that the developers of these instruments used the concept and definition for cyberbullying in different ways. Some examples of these varying concepts and definitions included Ybarra and Mitchell (2004) who used the concept of “online harassment,” which represented online behaviour that had the conscious intent to harm someone, yet only included intentionality, one of Olweus’ (1999) three criteria in the traditional bullying definition. Another example was the concept of cyberbullying as used by Raskauskas and Stoltz (2007), which included only intentionality and repetition. Conversely, Smith et al., (2008) presented the concept of cyberbullying with a definition that contained intentionality, repetition, and imbalance of power as outlined by Olweus’ principles. However, Corcoran et al., (2015) suggest that with the potential magnitude of audience accessing a content, a single cyberbullying incident could have a severe and ongoing detrimental consequence on the victimised person. Consequently, refining the definition as cyber-based aggression, could have serious implications for protecting mental health, as no longer would a young person have to tolerate several incidents of victimization before the behaviour could be accepted as cyberbullying. By eliminating the element of repetition from the conceptualisation of cyber aggression, it identifies the possibility for one single act to produce psychological harm to a targeted person.

However, the aspect of anonymity, the potential size of the audience and the limitless access to the victim, which are suggested characteristics specific to cyberbullying were not integrated into any of the 44 instruments’ definitions of cyberbullying (Smith, 2012). Furthermore, a cross-cultural study concerning five definitional criteria (intentionality, imbalance of power, repetition, anonymity, and publicity) for cyberbullying in six European countries (Menesini et al., 2012) revealed a first element categorized by imbalance of power and a second feature typified by intentionality and anonymity. Participants demonstrated a higher likelihood of identifying cyberbullying, if the episode was intentional and non-anonymous and a lower chance if the episode was non-intentional and anonymous. Thus, they emphasised the role of intention and anonymity as specific cyberbullying criterion. As a result of this finding, Menesini et al., (2012) suggested that cyberbullying should be studied under the more general definition of bullying, while simultaneously suggesting that the broad general definition can be challenging and disregards the specificity of cyberbullying. Of these 44 studies reported above, each study demonstrates a variation in the inclusion of the aforementioned elements of anonymity, intention, 24/7 exposure, and imbalance of power. The study by Mensini et al., (2012) also demonstrates the importance of these aspects. The omission of these elements can in itself lead to varying methodologies and may impact the prevalence rates reported by researchers cross-nationally.

OVERLAP OF CYBERBULLYING AND TRADITIONAL BULLYING

As the research on cyberbullying has developed, it has become evident that cyberbullying is no longer seen as completely separate to traditional bullying. Growing evidence from research has shown that rather than cyberbullying occurring in isolation to traditional bullying, there is in fact a degree of overlap (Olweus, 2012; Smith, Steffgen, & Sittichai, 2013). Research has indicated that cyberbullying is more common in European countries that have pre-existing high levels of traditional bullying, rather than in countries where the Internet is more established (Livingstone, Haddon, Gorzig, & Olafsson, 2010). This suggests that cyberbullying is another

aspect of the traditional bullying rather than something completely separate to it (Hinduja & Patchin, 2012; O'Moore, 2012). It would appear that technological advancement is, in effect, providing another podium for bullies to target victims. However, perhaps this is not the whole picture. While some overlap of the behaviour exists, other aspects are distinct from traditional bullying and it is vital that these aspects are examined by the research community. The literature is replete with examples of overlap of traditional bullying and cyberbullying (Juvoven & Gross, 2008; Katzer, Fetchenhauer & Belschak, 2009; Slonje & Smith, 2008; Smith et al., 2008). Ybarra and Mitchell (2004a) found that many cyberbullies were also cyber-victims, and that almost half of the cyber-bullies reported having been victims of traditional bullying. Research by Ybarra, Diener-West, and Leaf (2007) reported that 36% of children in a US sample simultaneously experienced traditional bullying and cyberbullying. Juvoven and Gross (2008) found that as many as 85% of children and teens who are cyber-victims were also victims at school. Traditional bullies were more than twice as likely to be both the targets and the perpetrators of cyberbullying, compared to those who do not engage in traditional bullying (Hinduja & Patchin, 2008), and victims of traditional bullying were 2.7 times as likely to be the victim of cyberbullying (Hinduja & Patchin, 2012). Canadian prevalence rates of students in grades 7-9 suggested that that one-third of those who cyberbullied were also traditionally bullied at school (Beran & Li, 2006). Kowalski, Giumetti, Schroeder, and Lattanner (2014) found that individuals can be targets in both the real world and online settings, and proposed that this offers "... support for the idea that cyberbullying can be considered an extension of traditional bullying" (p. 52). These rates suggest that cyberbullying and traditional bullying may be used in conjunction against the target. The perpetrator in one instance can be the victim in another circumstance and vice versa. Consequently, the importance of research cannot be underestimated when trying to analyse and resolve the behaviour of those involved in cyberbullying.

CROSS NATIONAL PREVALENCE RATES OF CYBERBULLYING

Regardless of the definitional concept and measurement approaches that have been utilised, a number of comprehensive studies have been conducted across the world in order to determine the prevalence rates of cyberbullying and determine the extent of the phenomenon. Explorations of the levels of cyberbullying have been conducted over the past few years and although the questionnaires used to assess cyberbullying differ, and this clearly impacts frequency rates (Rivers & Noret, 2010), the presence of cyberbullying in young people has been observed. In Australia, early research revealed almost 10% of 2,027 12 year old pupils from Western Australia had been sent hurtful messages on the Internet during the past school term (Epstein, Waters, & Cross, 2006). More recent research in Australia found that 6% of students reported that they were cyberbullied (every few weeks or more often), whereas less than a quarter (23%) reported being exposed to cyberbullying behaviours once or more often in the previous term. Similar differences were observed for cyberbullying others, where 3% reported that they cyberbullied others (every few weeks or more often) and 18% reported that they engaged in cyberbullying behaviours at least once in the previous term (Cross et al., 2011). In Britain, Smith et al., (2008) reported that a total of 22% of the participants between the ages of 11 and 16 years had been cyberbullied, where 15.6% of participants reported that the

victimisation occurred once or twice and 6.6% of these had been cyberbullied on a frequent basis. Li (2010) sampled participants from both China and Canada and revealed that 15% of Canadian participants were classified as cyberbullies compared with 7% from the Chinese sample. In Ireland, research with respondents aged 12-16 years found that 2.6% admitted to cyberbullying on at least one occasion, 6.3% had been cyber-victimized at least once, 4.3% admitted to cyberbullying others almost every day, and 5.5% reported being cyberbullied almost every week (Corcoran, Connolly, & O'Moore, 2012). Further research reported that around one in seven students (14%) reported being cyber-bullied in the past couple of months. One in 11 (8.7%) reported that they had cyberbullied others (O'Moore & Minton, 2009). Additional European data from the EU Kids Online research of 25,000 9-16 year olds across 25 European countries revealed that cyberbullying rates were highest in the 15-16 age group at 8% compared with 3% for the 9-10 year olds (Livingstone et al., 2010). In the 13-16 year old group only, the girls were cyberbullied more (9%) than boys (6%). Further European research carried out by Net Children Go Mobile (Mascheroni & Olafsson, 2014) found that 12% experienced online bullying, an increase from previous studies carried out in member states.

In the US several studies have provided prevalence rates. Early research by Ybarra and Mitchell (2007), in a telephone survey of 1,498 Internet users (10–17 years old) found that 19% of the adolescents had been involved in cyberbullying either as cyber-bullies or cyber-victims in the previous year. In a further study of 3,767 middle-school students of grades 6 to 8, Kowalski and Limber (2007) found that 11% were cyber-victims, 7% were cyber-bullies/victims, and 4% were cyberbullies. The majority (78%) had no experience of any form of cyberbullying. In a summary of their extensive work on cyberbullying in the US, Hinduja and Patchin (Patchin & Hinduja 2006; Hinduja & Patchin, 2008, 2010, 2012) found that (on average), about 25% of the students who had been a part of these studies reported that they had been the victim of cyberbullying at some point in their life-time. The rates of cyberbullying others varied throughout the research. However, an average of 16% of the participants, admitted that they cyberbullied others at some point in their lifetime. Kowalski and Limber (2013), in a study of 918 individuals between the ages of 11 to 19 years, examined cyberbullying. Prevalence rates using the conventional criterion of two or three times a month or more, and the more copious criterion, of at least once in the previous 2 months revealed the following: 10% reported having been cyberbullied at least once in the past couple of months. Six per-cent stated that they had cyberbullied others within the last couple of months. Just over 5% reported that they had cyberbullied others and had been cyberbullied. The research above provides evidence of the existence of cyberbullying cross-nationally, with many countries reporting cyberbullying amongst young people. However, the evidence does not support the notion of a rapid increase in prevalence rates as many media outlets have reported.

Much of the research regarding young people's involvement in cyberbullying varies. Research suggests that prevalence rates are not increasing exponentially. The results for four consecutive years of the US sample of 440,000 participants (Kowalski & Limber, 2007- 2010) revealed that whilst 4.5% were cyber-bullied, 2.8% cyberbullied others. Norwegian data with prevalence figures from 41 schools, over a five-year period from 2006 to 2010, show a very similar pattern of results but at somewhat lower prevalence levels (Olweus, 2012). The average figure for being cyberbullied was 3.4% and for cyberbullying others was 1.4%. In addition, Jones, Mitchell, and Finkelhor (2013) collected data from students across the US in 2000, 2005, and 2010 and reported a modest but steady increase in cyberbullying between 2000 and 2010 (from 6% to 11%). However, variation was dependent on samples, definition, and

measurements used. In a review of 35 papers that were published in peer-reviewed journals, Patchin and Hinduja (2012) found that, on average, 24% of students had been cyberbullied and 17% of students admitted to engaging in cyberbullying behaviours. A longitudinal study in Finland (based on the KiVa program) which involved 17,000 participants suggested that electronic bullying is actually quite rare. Indeed, Salmivalli, Sainio, and Hodges (2013) argued that based on rigid criteria which applied to both traditional and cyberbullying, the timeframe of taking place two or three times a month or more often, that bullying is rare, with only 2-3% of students reporting being cyber-victims. Now that the existence of cyberbullying cross-nationally has been established, it is important to investigate the methodologies employed in the cross-national research, which may contribute to the varying prevalence rates.

FACTORS INFLUENCING METHODOLOGIES OF CYBERBULLYING RESEARCH

One of the largest differences in the collection of prevalence rates of cyberbullying is the differing methodologies employed. As mentioned previously, the various definitions in use by researchers is one of the first issues that arises. Ybarra (2014) referred to inconsistencies regarding how the behaviour is ascertained and comprehended within studies. Variation occurs where a definition is provided within a questionnaire, when lists of behaviours are provided, or in some case neither of these is provided. Of 61 studies reviewed by Smith (2012), almost half of the instruments used to examine cyberbullying, did not actually use the concept *cyberbullying*. They ranged from internet harassment behaviour, to electronic bullying behaviour, to cyberbullying. The concept of cyberbullying was only included in 21 of the 44 instruments, and 24 of the 44 instruments included the concept cyber-victimization. This exemplifies that there is a variation of the concepts used in the instruments measuring cyberbullying. A similar finding emerged from another systematic literature review of cyberbullying instruments and measures carried out by Frisé et al., (2013). This review further established that almost half of the instruments used to measure cyberbullying did not use the concept of cyberbullying in the methodology, but actually measured associated constructs such as Internet harassment. Again, this demonstrates that researchers are not content with the definitions in existence and are looking to the behaviours evidenced or experienced by victims of cyberbullying. Furthermore, the rapid advancement of technology also effects the methodologies of studies. In early research, texts and phone calls were seen as separate entities to the Internet/computer. Essentially a smart phone is a hand held computer, providing access to social media in an instant. However, this technological distinction has now been abandoned by many researchers, with focus adapted to concentrate more on the different types of behaviour such as: flaming, insulting, text messaging, using pictures and videos, exclusion, and misappropriation of personal information or passwords (Menesini, 2012). The methodologies employed in some cyberbullying research has been lagging behind the technological advancement. In earlier research, experts advised parents to keep the family computer in a family room, but within a few short years this advice is obsolete. Young people can access the Internet, wherever Wi-Fi exists, which in today's society, is a great number of places. Young people arriving into a restaurant or café, even the cinema, automatically check for Wi-Fi access and actively search it out. In fact, the implication of technological prowess differing amongst

young people is also practically obsolete. As long as research lags behind the developing technology, prevention techniques will also lag behind. Smith's (2012) review reported that the technology assessed in the cyberbullying instruments varied considerably: a total of 34 devices/media were assessed in the instruments, with mobile phones (24 of the 44 instruments), and e-mail (21 of the 44) being included most. The majority of young people now communicate via social networking messaging and other social media apps over Wi-Fi rather than e-mail. The move from texts to email, and to social networking sites, the role of smartphones and tablet devices, alongside any newer technological developments will need to be examined more in further research, alongside the impact these differing technological devices will play on prevalence rates. Gaming is also an important factor today. Children and young people are playing online games with a variety of people, some known to them and others that are not. With cyberbullying occurring through this medium, little of the research is focusing on this aspect of social media interaction. Therefore, it is important to stay abreast of new types of devices/media when measuring cyberbullying experiences (Smith, 2012).

Further analytical difficulties in relation to prevalence rates of cyberbullying is the difference in the age ranges of the participants, with some studies examining those under the age of 10 years and others concentrating on adolescents (Tokunga, 2010). Unpredictable findings can result from the diverse range of age groups included within samples. For instance, Kowalski and Limber (2007) and Ybarra, Mitchell, Wolak, and Finkelhor (2006) demonstrated positive associations between age and frequency of victimization in their studies examining 11 to 14 year olds and 10 to 15 year olds, respectively. Slonje and Smith (2008), in contrast, uncovered an inverse relationship between age and victimization in their sample of 12 to 20 year olds. Similar negative trends are reported in other studies also (Dehue, Bolman, & Völlink, 2008). By contrast, in research carried out by Williams and Guerra (2007) of fifth, eighth, and eleventh graders, the results found that fifth graders experienced the least victimization, with a prevalence rate of 4.5%. Those who had been cyber-victimised the most of the three age groups, were the eighth graders (12.9%) and the high school students falling between these groups (9.9%). Some researchers have also employed cartoons to represent bullying and cyberbullying for younger ages (Joint Select Committee on Cyber-Safety, 2011). This also has repercussions for determining prevalence, as developmentally diverse age groups need distinct methodologies, in order for researchers to figure out their perceptions of the behaviour. Young children can amalgamate their experiences and this can cause difficulties in retrieving the information (Smith, Cowie, Olafsson, & Liefvooghe, 2002). Collectively, the data suggested that these diverse results may be credited to a curvilinear relationship between age and frequency of victimization (Juvonen & Gross, 2008; Katzer et al., 2009; Patchin & Hinduja, 2006; Smith et al., 2008; Wolak et al., 2007; Ybarra, 2004). It makes sense that different age groupings would reveal different results, therefore the research will need to compare within similar age groups to establish true prevalence rates rather than across a variety of age groups. The time reference period, is a key issue in determining prevalence of cyberbullying, with some research including timeframes such as *last month*, *last term*, *last year* or *ever at school* (Monks et al., 2009). This judiciously impedes cross-study and cross-cultural evaluations. Solberg and Olweus (2003, p. 243) suggested that "... every couple of months is a reasonable "memory unit" for students to recall traditional bullying, but no consensus has been arrived at with regard to cyberbullying". These cut-off points for the establishment of groups and sub-groups is vital to evaluating prevalence. In traditional bullying research Olweus (1999) queried bullying levels in relation to the "last couple of months" followed by a series of choices as to frequency, which

included: *not been bullied; only happened once or twice; two or three times per month; about once a week; several times a week*. The cut-off point has usually been *2–3 times a month*, as this indicates repetition and the bullying being ongoing over time (Olweus, 1999). In cyberbullying research, however, there appears to be a shift towards a lower cut-off point: *it has happened once or twice* (Frisén et al., 2013). A lower threshold for categorisation such as “*once or twice*” makes it more challenging to find significant and reliable models of results (Olweus, 2012). Such a strategy is also likely to end up with more chance findings leading to less consistency. This has consequences for establishing prevalence across studies. The longer the timeframe used, the greater the number of people who will have had the experience in question. Some studies have asked participants about *any* experience with cyberbullying, while others have focused on those who have experienced specific types of high-tech harm within the *previous 30 days* (Sabella, Patchin, & Hinduja, 2013). Other studies restricted the time frame in which the cyberbullying could have occurred (Dehue et al., 2008; Williams & Guerra, 2007; Wolak et al., 2007; Ybarra & Mitchell, 2004, 2008), naturally diminishing the prevalence rates of victimization.

Another issue is the varying methodologies used in data collection, with national random telephone surveys, online random surveys, online self-selected surveys or offline convenience samples having all been used. Methodologically, self-report instruments with close-ended questions used in the research of traditional bullying have influenced the design of instruments measuring cyberbullying (Tokunaga, 2010). Self-report questionnaires have advantages for researchers, due to their ability to gather large amounts of data in a relatively short time frame. They are quick and easy to administer and acquire the respondents’ views directly. Furthermore, it is a good way to measure the respondents’ perception of the construct measured (Streiner & Norman, 2008). However, precise self-report data are challenging to achieve, as there is frequently an inclination for young people to under-report deviant behaviour or to reply in socially desirable manners. In Smith’s (2012) methodological review of 44 studies of cyberbullying, 41 used self-reported questionnaires. Additionally, two out of the 44 studies contained data from both focus groups and self-report questionnaires (Smith et al., 2008; Wright, Burnham, Inman, & Ogorchock, 2009). In relation to reliability and validity of self-report questionnaires used, only 18 out of the 44 studies reported the instruments reliability, these only reported on internal reliability/consistencies. The review also found little evidence of test validity. Convergent validity data was reported in only 24 out of the 44 instruments. Future research on cyberbullying must emphasise the development of valid instruments which allow researchers to consistently measure the same phenomenon. Some questionnaires used are discussed below.

Instruments involved in gathering rates of cyberbullying vary tremendously cross-culturally, with several researchers designing their own specific instruments. One of the most widely used instruments is the *Revised Olweus Bullying Questionnaire* (Olweus, 1996), which provides participants with a detailed definition of bullying and 39 key questions. Since 2005, a question about cyberbullying with two sub-questions about mobile phone or Internet has been added. Several empirical and conceptual analyses have verified the functionality, construct, and concurrent validity of the two global questions (Olweus, 2010; Solberg & Olweus, 2003) and a scale of bullying others using item response theory analyses (Breivik & Olweus, 2012). This examines cyberbullying within the context of traditional bullying, as does the Smith et al., (2008) *Cyberbullying Questionnaire*, and the Slonje and Smith (2008) *Cyberbullying Questionnaire*. This method of data collection is promoted by Olweus (2012) who suggested

that the high prevalence rates of some research may be due to the fact that data collection occurred in isolation to traditional bullying research. However, others have examined cyberbullying as a stand-alone issue. Some of these included *The Cyberbullying Questionnaire* (Calvete, Orue, Estévez, Villardón, & Padilla, 2010), *The Revised Cyberbullying Inventory* (Erdur-Baker, 2010), *Cyberbullying Student Survey* (Li, 2010), *Cyberbullying Scale* (Menesini, Nocentini, & Calussi, 2011), and *Cyberbullying and Online Aggression Survey Instrument* (Patchin & Hinduja, 2006). Menesini (2012) proposed that cyberbullying can be deciphered as a uni-dimensional measure, where items fall on a spectrum of aggressive acts (Menesini et al., 2011) and hence, in contrast to Olweus' (2012) suggestion that cyberbullying should not be examined in isolation to traditional bullying. Furthermore, extrication of prevalence of traditional bullying from cyberbullying is also challenging, due to the positive correlations which have been found between traditional and cyberbullying, in terms of bullying and being bullied (Sourander, Klomek, & Helenius, 2010). Cyberbullying incidence is often examined in the form of one or two item measures, which are based on yes/no responses (Ybarra, 2012). Numerous difficulties materialise concerning this type of methodology. First, cyberbullying is a complex construct, which makes a yes/no response difficult to decipher. Researchers are relying on a child's ability to understand multifactorial definitions and their ability to respond to the one or two item measure regarding those multifactorial elements (Tokunga, 2010). Secondly, issues of reliability are evident with the use of the one or two item measures, as single items are often less reliable than multiple-item instruments (Smith, 2012). Single items have been found to have greater chance of random error, and response biases such as social desirability, whereas increasing the number of items in a measure has the effect of increasing the reliability of that measure (Murphy & Davidshofer, 2005). Thirdly, single items can only differentiate moderate to large differences (Griezel, Craven, Yeung, & Finger, 2008) but lack scope and the ability to expose detail (Farrington, 1993; Smith, Schneider, Smith, & Ananiadou, 2004).

The true prevalence rates of cyberbullying have been disputed by many researchers (Hinduja & Patchin, 2012; Olweus, 2012; Smith 2012). Media reports have highlighted the problem of cyberbullying but empirically based evidence is essential to analyse the success or failure of intervention programs. There appears to be important national or cultural differences evident in cyberbullying (Li, Cross, & Smith, 2011). Many factors discussed above play a role in the differing rates, including the educational systems, local and national anti-bullying and cyberbullying policies, the nature of the society, and the emergence of new technologies (Smith, 2012). The differences that exist between cultures is an important aspect of the variation, however, the lack of consistency between instruments is dramatic. This in itself will continue to result in large differences. It is perhaps a variation that we have to accept. However, when variation continues to occur across national surveys, then the instruments in use in these studies may need to be considered seriously. However, there exists agreement amongst researchers regarding the negative effects of being cyberbullied (Smith et al., 2008). Early research by Beran and Li (2005) found the following psycho-social outcomes of being the victim of cyberbullying. The cyber-victims reported anger, anxiety and feeling sad, but the cyber-victims also reported that they found it difficult to concentrate in school, affecting both their learning ability and their consequential success at school. In addition, Hinduja and Patchin (2009) in a study of almost 2000 middle school students in the US also found that the cyber-victims reported similar effects of anger, and sadness, but also being frustrated and even scared following a cyberbullying episode. In addition, this research revealed that the self-esteem of

both the cyberbullies and cyber-victims was lower than their counterparts who were not involved in bullying. These psycho-social consequences can also be accompanied by mental health issues, where Ybarra (2004) reported a link between cyber-victimisation and depressive symptoms. A similar finding was also reported by Kessel Schneider, O'Donnell, Stueve, and Coulter (2012) who highlighted the connection between victimisation and psychological stress. Their research found that one-third of students who were cyberbullied in the past 12 months reported symptoms of depression, a figure which rose to nearly one-half for those who experienced both cyber- and traditional bullying.

CONCLUSION

Alongside the outcomes for those involved in cyberbullying, the research on prevalence of traditional bullying is of great importance. Much of the research into cyberbullying has been conducted by psychologists, but both sociologists and lawyers can play a big role in the understanding of cyberbullying consequences, such as the sociological perspective of the bystander in cyberbullying and the legal implications of cyberbullying others. Smith (2012) stated that developmentally, cyberbullying may demonstrate more penetrability than traditional bullying as it takes place in cyberspace. Therefore, developmental changes in cyberbullying may be less confused by situational changes than for traditional bullying. Despite media coverage of tragic cyberbullying cases, the research community finds evidence that traditional bullying occurs at a far greater level than cyberbullying (Hinduja & Patchin, 2012; Smith, 2012). The exposure of cyberbullying in the media has brought greater knowledge of this phenomenon to students, parents, and educators, with the knowledge of intervention techniques spreading, as a result of the awareness linked to cyberbullying (Smith, 2012). Researchers need to pay attention to the rapidly developing technology and its impact on cyberbullying prevalence levels. Bearing this in mind, intervention programmes must be designed to deal with both traditional bullying and cyberbullying and not an over emphasis on one aspect over the other. Much cyberbullying research focuses on the prevalence rates, but rarely is the duration of the victimization examined (Aricak et al., 2008). Additionally, acquiring information about the average length of time between each cyberbullying encounter could provide a greater understanding of cyberbullying and its effects (Tokunga, 2010). The aim of future research on cyberbullying needs to focus on the development of a reliable and valid measure of the cyberbullying construct. Valid and reliable measures improve the overall quality of research; the value of an effective scale, depends on the transparency and intensity of the theoretical definition from which it originates. In the case of cyberbullying research, measures are unable to thrive in the dearth of a unanimously-agreed definition (Tokunga, 2010). Further consideration will need to examine the differences in educational systems, local and national anti-bullying policies and the nature of the society. One final last point regarding the prevalence rates of cyberbullying, is that while there does not appear to be an exponential increase in cyberbullying cross-nationally, we are also not finding much evidence of decreasing levels of cyberbullying either. This in itself is of great concern and emphasises the need to delve further into the world of cyberbullying in order to reduce these prevalence rates.

Chapter 139

CYBERBULLYING AMONG CHILDREN AND ADOLESCENTS: A QUANTITATIVE AND A QUALITATIVE APPROACH TO GENDER DIFFERENCES

Raúl Navarro^{*}, Santiago Yubero and Elisa Larrañaga

Department of Psychology, University of Castilla-La Mancha, Cuenca, Spain

INTRODUCTION

In the last decade, researchers who study bullying behaviours have shown increased interest in cyberspace since the Internet may be a fertile ground for cyberbullying (Juvonen & Gross, 2008). One definition of cyberbullying states that it includes “. . . any behavior performed through electronic or digital media by individuals or groups that repeatedly communicates hostile or aggressive messages intended to inflict harm or discomfort on others” (Tokunaga, 2010, p. 278). Like traditional bullying, cyberbullying is an aggressive act between peers, characterised by (i) imbalance of power (provided by perpetrators’ anonymity or different grades of technological expertise), (ii) negative intentions and (iii) repetition. Among the growing number of studies conducted, those that sought to learn about the personal and social factors that make youths more vulnerable to suffering or perpetrating cyberbullying stand out. The main interest in analysing these factors lies in knowing in detail the characteristics associated with such aggression and, thus, improving the efforts made to prevent and intervene in it when it occurs. Among the examined factors, gender is present in most of these studies. Indeed, most research that works on such problems has analysed gender differences, even when this was not their main objective.

Consequently, this chapter examines the role of gender in cyberbullying incidents carried out by children and adolescents, by reviewing international research which has linked cyberbullying with gender studies. To this end, we first briefly review the concept of gender and the predominating theories that have analysed how learning the traits, roles and preferences associated with the male and female social categories comes about, which may contribute

^{*} Corresponding Author’s Email: raul.navarro@uclm.es.

differences in the involvement of males and females in cyberbullying. Second, we review the research that has explored gender differences for cyberbullying involvement, and we also examine cyberbullying that addresses members of the same or the opposite sex. Finally, we analyse how cyberbullying can be a form of aggression in dating relationships, and also a way to retaliate after a romantic relationship ends. Throughout this chapter we accompany theory with a description of studies conducted in different countries, and to present new quantitative and qualitative data to illustrate the role that gender plays in cyberbullying.

GENDER AS A CULTURAL CONSTRUCT AND ITS RELATIONSHIP WITH AGGRESSIVE BEHAVIOURS

In order to know the extent of the relationship between gender and aggressive behaviour, like cyberbullying, first it is important to delimit what we refer to when we talk about gender. The first thing we must consider is that gender is a social category (males and females) which people can distinguish from a very early age, and is not just a product of our biology. Consequently, we use this relevant information to structure our social world. Gender includes stereotypical beliefs about personality traits (e.g., males are meant to be independent, tough and assertive, and females are emotional, sensitive and people-oriented), roles (e.g., males as a defender of the family and companions; females as nurturers and caregivers), and preferences (e.g., males show more interest in watching sports, and females in shopping). In other words, when we talk about gender, we refer to a collective imaginary which, despite being different between cultures, defines what is masculine and feminine, and indicates how males and females must behave (Eagly & Wood, 1999; Matud, 2004).

Gender studies have attempted to understand how individuals acquire these preferences, behaviours, interests, skills, and even personality traits, which are more typical of their own sex. The gender-typing process is the name given to the acquisition of these features, and the two most relevant theories that analyse such processes are the Social Learning Theory (Bandura & Bussey, 2004; Bussey & Bandura, 1999) and the Self-Socialisation Theories (Halim, Ruble, Tamis-LeMonda, & Shrout, 2013; Martin & Ruble, 2010).

According to Social-Learning Theories (Bussey & Bandura, 1999), acquiring gender schemata takes place through direct socialisation in which various agents (e.g., parents, teachers, peers) provide rewards or punishments that reinforce gender-appropriate conduct, but also through observing relevant or powerful models similar to young people, either at home or at school, in the peer group or via the media (Bandura & Bussey, 2004). From this theory, the interest is in the social-interactive processes where gender is recreated and learnt.

The Self-Socialisation Theories of gender development argue that both genders actively seek gender-related information which serves as a guide for their own conduct, and contributes to their own socialisation (Halim et al., 2013). During this process, children are active as they seek information that may, or may not, be congruent with gender stereotypes depending on the individual, the social context, and on other conditions that make gender a salient variable, such as peer pressure (Halim, et al., 2014).

Both gender learning explanatory models underline the importance of two socially distinct groups existing (males and females) surrounded by a series of traits, roles and stereotyped conduct, that may influence the way we act in personal relationships and how we construct

reality. The time has come to consider to what point we identify ourselves with the masculine and the feminine group, and to also wonder about how learning typified conduct per gender influences our aggressive behaviour, and specifically cyberbullying.

In line with the arguments put forward to date, research has proposed that differences in aggressive conduct can be influenced, to a point, by gender socialisation, but specifically by learning instrumental (masculine) or expressive (feminine) traits. According to these traits, men must be assertive, aggressive, brave and independent, whereas women must be sensitive, emotional, friendly and caring in relations. So it seems that gender socialisation indicates that for males, aggression is useful for maintaining their gender role, while aggression for females should be inhibited, or females should employ more indirect forms because they would better stereotypically match the feminine role (Underwood, Galen, & Paquette, 2001). Other researchers point out the possibility that the different implications of males and females in aggressive and antisocial conduct relates to gender differences in cognitive abilities according to differential socialisation. For example, research acknowledges that females acquire social cognitive skills much earlier in life than males and may, consequently, have superior skills (Bennett, Farrington, & Huesman, 2005). These cognitive abilities might result from placing, in socialisation, greater emphasis on empathy, social reasoning, perspective taking and social problem solving, which can protect from behavioural difficulties and antisocial attitudes (Bennett et al., 2005).

An established risk factor for suffering aggression is gender. Specifically, females are at greater risk of experiencing violence as a result of reproduced cultural hierarchies of power related with gender socialisations, where men occupy a better position in society than women. From this perspective, girls are inherently more at risk of being victimized because of their disadvantaged position in society. For example, Navarro and Jasinski (2013) argue that girls may be subject to higher rates of cyberbullying victimization because of their already disadvantaged position on the Internet.

THE ROLE OF GENDER IN CYBERBULLYING AMONG CHILDREN AND ADOLESCENTS

Most research done on cyberbullying has focused on analysing the prevalence, correlates and antecedents of these online behaviors in youths by attending primary and secondary schools (Wingate, Minney, & Guadagno, 2013). Regarding gender, research into gender differences in cyberbullying took the results found in traditional bullying as a starting point. In this section, we review gender differences in traditional bullying and examine international research on gender differences in cyberbullying. We also offer new data from the studies we have conducted in Spain about overall gender differences in cyberbullying, differences in specific forms of cyberbullying, and the perceptions of pre-adolescents and adolescents about cyberbullying as a gender-typed behaviour.

Gender-Based Differences in Cyberbullying

Traditional bullying includes forms of physical, verbal and relational aggression. Relational aggression strategies refer to a kind of social manipulation in which the perpetrator uses a peer group to attack a victim and encompasses behaviours where damage to relationships is used as a means to hurt others (Crick & Grotpeter, 1995). According to Artz, Nicholson, and Magnuson (2008), relational aggression has been applied to face-to-face behaviours like actions such as keeping someone out of a group, saying you will not be friends with someone, ignoring a person, telling rumours or lies about someone you are mad at, threatening to end a friendship or no longer talking to someone. Relational aggression also includes covert behaviours like indirectly excluding or socially manipulating a person by using another's relationship with that person as the vehicle for harm.

For a long time, research has tended to show that males generally employ more verbal and physical bullying than females, who tend to resort to more relational forms. Several reasons have been pointed out to explain gender differences reported in the past literature, among which: (i) females use indirect forms of aggression because they learn that adults frown on direct forms of aggression (Björkqvist, Lagerspetz, & Kaukianen, 1992). Simmons (2002) shares this opinion when he talks about the influence of gender socialisation and how females emphasize more emotions and interpersonal events, which inhibit direct aggressive conduct; (ii) the social structure that groups of females adopt is smaller and more intimate compared to males. This fact implies that indirect aggression is more effective (Björkqvist, Österman, & Kaukianen, 2000) and; (iii) the social intelligence of girls aged 9-11 years is more advanced, which relates with a better use of manipulation strategies in interpersonal relations (Bennet et al., 2005). Indeed, research has pointed out that females get involved in such conduct because they are better at hurting for something that their own gender values more: friendship (Huntley & Owens, 2013, Jennifer, 2013).

However, a recent meta-analysis has shown that males are more involved than females in any form of conventional bullying, and in bullying roles as victims or bully-victims (Cook, Williams, Guerra, Kim, & Sadek, 2010). Furthermore, several studies reveal that, despite previous evidence, no gender differences exist when using relational strategies (Archer, 2004; Card, Stucky, Sawalani, & Little, 2008; Toldos, 2005). All of these studies conclude that males and females do not differ significantly in their use of relational aggression in pre-adolescence and adolescence. Males employ any form of aggression to a greater extent than females. More recent studies have even shown that males have exceeded females in using relational aggression (Artz, Kassis, & Moldenhauer, 2013). These results should help to refute the characterisation classically made of females as being more manipulative and resorting more to spreading rumours, which has made such aggression inherent to the female nature (Horn, 2004).

Therefore, it is not possible to simplify such a complex phenomenon like bullying, in which we need to consider the existence of individual variability, and also the influence that the social context has on our conduct. People mostly use various types of aggression depending on surrounding demands. From this perspective, aggression provides a series of tactics that function for different social objectives. Although the willingness of each person to act aggressively differs, its incidence must be seen in the social context where people interact (Underwood, 2003).

Despite empirical evidence providing contradictory results, the generalised belief that females use more relational aggression forms, as part of conventional bullying, than males

apparently still persists (Kowalski, Giumetti, Schroeder, & Lattanner, 2014). This belief, along with cyberbullying described as a type of psychological and emotional abuse performed by means of diffusing information over the Internet where the aggressor remains anonymous (Beran & Li, 2008), has led to research on such relational aggression starting from the premise that it is a form of bullying employed more by females (Dooley, Pyżalski, & Cross, 2009; Tokunaga, 2010). However, empirical evidence has not always backed this premise. In fact, far from providing a clear gender pattern of involvement as perpetrators or victims, research has provided mixed results.

The next section will present, along with a review of international research, some new data obtained with Spanish pre-adolescents, which will enable us to analyse the role of gender in cyberbullying.

Overall Gender-Based Differences in Cyberbullying

In Spain, as in other countries, studying the prevalence of cyberbullying according to participants' gender has produced mixed results (Buelga, Cava, & Musitu, 2010; Estevez, Villardón, Calvete, Padilla, & Orue, 2011). The majority of studies have focused more on analysing gender differences in secondary education students rather than in primary education pupils. In order to verify if there are gender differences in pre-adolescents' involvement in cyberbullying, we analysed gender differences in a sample of Spanish students, where we took gender to be a self-assignment of one category (male – female) or another (Navarro, Larrañaga, & Yubero, 2016). The participants were 445 school pupils who were in grades 5 and 6, who we sampled randomly from four primary schools. These schools were located in a city of central Spain, with an approximate population of 60,000 people. Participants included 208 girls ($M(\text{age}): 10.78, SD=0.74$) and 237 boys ($M(\text{age})=10.78, SD=0.68$). All of the children studying grades 5 and 6 were eligible to participate in the study. We recruited the children whose parents agreed they could participate, and obtained complete data from 445 of the 500 questionnaires distributed. We measured cyberbullying victimization (CBQ-V, Estévez et al., 2011) and cyberbullying perpetration (CBQ; Calvete, Orue, Estévez, Villardón, & Padilla, 2010). The data was collected at the end of the 2013/2014 academic year.

Participants were categorised as victims or bullies by following a highly restrictive criterion. We classified those students as victims who indicated experiencing, but not perpetrating, at least one of the behaviours included in the questionnaire several times a week. We classified those students as bullies who reported perpetrating, but not experiencing, at least one of the behaviours several times a week. We considered the remaining students as not being involved in bullying. This procedure resulted in 52 (11.6%) children categorised as cybervictims and 37 (8.3%) as cyberbullies. Table 1 shows the distribution of cyberbullying involvement according to gender.

Table 1. Distribution of males and females among cybervictimization experiences

	Non victims	Victims	Non perpetrators	Perpetrators
Females	187 (89.9%)	21 (10.1%)	199 (95.7%)	9 (4.3%)
Males	206 (86.9%)	31 (13.1%)	209 (88.9%)	28 (11.8%)
Total	393	52	408	37

Chi square analyses were conducted to examine if there were any statistically significant differences among study variables. Significant differences were found, with more males than females reporting that they were frequent perpetrators (χ^2 (df 1) = 8.14; $p < .005$). Also, no gender differences were uncovered in relation to the victim role (χ^2 (df 1) = 0.95; $p = 0.376$). Here we wish to stress to readers the fact that, by assuming that this difference exists as regards the perpetrator's role, by following the Social-Cognitive Theory (Bussey & Bandura, 1999), we argue that this difference might be due to a distinct gender socialisation, as females develop more empathic capacities and get less involved in antisocial behaviour (Bennet et al., 2005). In parallel, cyberbullying as an aggressive conduct can be useful for maintaining the masculine gender role. That is to say, males can display adherence to certain traits linked to the classic masculine identity, like aggression, power, or arrogance. Nevertheless, it is difficult to corroborate these conclusions because we have not specifically analysed these variables. Thus, we should study the influence of gender on cyberbullying by ascertaining the factors relating to the social and cultural expectations of gender, which lead males to become more involved as perpetrators (see Navarro, 2016).

We can add our results to several trends in international research (see Navarro, 2016 for more details of studies that analyse gender differences in cyberbullying). Generally speaking, some researchers have found that males are more aggressive than females, but females are more victimized than males (e.g., Ayas, 2014; Barlett & Coyne, 2014; Låftan, Modin, & Östberg, 2013). Other studies have reported that males act more as perpetrators, but with no significant differences in victimization (Smith, Thompson, & Bhatti, 2012). Other studies have found that females act more as perpetrators and victims than males (Mark & Ratliffe, 2011), or more males are the perpetrators and victims (Fanti, Demetriou, & Hawa, 2012). Some studies have found no gender differences in either perpetrators or victims (Griezel et al., 2012; Hinduja & Patchin, 2008). Overall, the literature on gender differences in cyberbullying indicates that more research needs to be conducted before drawing conclusions.

Gender-Based Differences in Specific Types of Cyberbullying

As overall gender differences are lacking, authors like Underwood and Rosen (2010) express the need to analyse gender differences in the specific forms of cyberbullying employed by one gender and the other. Several authors have performed this task to find some gender differences in the forms of cyberbullying employed or received. Nonetheless, the results are sometimes mixed and comparing studies is a complicated issue because they have used several different measurement instruments, and not all studies have analysed the roles of perpetrators and victims. Some of these studies have examined gender differences in the form of cyberbullying practiced with cell phones (e.g., text messaging, phone calls) or over the Internet (e.g., e-mail, IM applications). This group of studies includes the work of Kapatzia and

Syngollitou (2007), conducted in Greece, which found that males were more involved as perpetrators using cell phones, while females were more implicated in cyberbullying over the Internet. A study by Smith et al. (2012) in England, revealed that males get more involved as bullying perpetrators both on the cell phone and over the Internet than females. They failed to find differences in the role of victims. Also in England, Monks, Robinson, and Worlidge (2012) found that girls were more likely to use email and instant messaging to cyberbully, while boys were more likely to use text messaging. In Belgium, Vanden Abeele and De Cock (2013) discovered that females were more likely to engage in indirect cell phone bullying (e.g., gossiping) than their male counterparts. However, they found no gender differences between males and females in direct cell phone bullying (e.g., using a phone call to insult someone).

Another set of studies analyzed gender differences in specific cyberbullying practices. In Belgium, Vandebosch and Van Cleemput (2009) reported that males were significantly more likely to admit their participation in several types of cyberbullying, like making threats or insults and spreading rumors by e-mail and/or phone. In Spain, Calvete et al. (2010) observed that boys were significantly more likely to record and send images of physical aggression, record humiliating images of a classmate, and send images of a sexual nature of classmates. In the US, Kowalski and Limber (2013) found that particular types of cyberbullying (e.g., video gaming) were more likely to affect males than females. Also in the US, Connell, Schell-Busey, Pearce, and Negro (2014) reported that females were considerably more likely than males to report engagement in, and victimization by, every mode of cyberbullying examined. In New Zealand, Fenaughty and Harré (2013) indicated significant gender differences between the Internet (e.g., use of social networks, IM applications to cyberbully) and cell phone harassment (e.g., use phone calls or texting to cyberbully). Males were significantly more likely to report being more victimized receiving scary or disgusting images, or having mean or embarrassing images of themselves sent to others. Female participants were more likely to report victimization involving mean, nasty or hurtful comments.

After considering the studies reviewed, we analysed gender differences in specific forms of cyberbullying between victims and perpetrators in the aforementioned sample. In our case, as shown in Table 2, we found gender differences only in two cyberbullying practices with male participants, who reported that they were more likely to send threatening or insulting messages by cell phone, and being victims of recording a video or taking pictures by cell phone when someone hits or hurts them, compared to their female counterparts.

The results obtained in international research and the data provided herein do not allow us to conclude that a clear gender difference exists in the various forms that cyberbullying takes. However, they allow us to draw some conclusions. First of all, whereas in traditional bullying males are more victims and perpetrators compared with females, in cyberbullying a clear difference between males and females is missing. This result indicates that more females are victims of cyberbullying than conventional bullying, as indicated by previous research (Kowalski, Morgan, & Limber, 2012). Second, more males apparently tend to exercise and suffer the form of cyberbullying that employs humiliating images or contains physical aggression than females. Males also tend to send more sexual or pornographic images, which is a form of cyberbullying to which females are more exposed, according to previous studies (Cassidy, Brown, & Jackson, 2012). These new forms of sexual and gender harassment require more research effort, which could be essential to understanding the role that gender plays in cyberbullying. Next, we analyse such aggression types in more detail.

Table 2. Prevalence and type of cyberbullying experiences per gender (n=445)

		Females		Males			
Type of cyberbullying	Role	M	SD	M	SD	t(1, 443)	d
Receiving or sending threatening or insulting messages by e-mail	Victim	1.20	0.69	1.17	0.61	0.389	0.04
	Perpetrator	1.09	0.45	1.14	0.58	-0.954	-0.09
Receiving or sending threatening or insulting messages by cell phone	Victim	1.29	0.76	1.22	0.67	1.078	0.09
	Perpetrator	1.13	0.50	1.24	0.75	-1.876*	-0.17
Posting on the Internet or sending humiliating images	Victim	1.05	0.31	1.05	0.33	0.209	0
	Perpetrator	1.02	0.24	1.06	0.33	-1.226	-0.13
Writing embarrassing jokes, rumors, gossip, or comments on the Internet	Victim	1.26	0.80	1.33	0.88	-0.803	-0.08
	Perpetrator	1.17	0.68	1.27	0.79	-1.374	-0.13
Hacking to send messages by e-mail or social networks	Victim	1.17	0.65	1.14	0.51	0.690	0.05
	Perpetrator	1.12	0.53	1.18	0.69	-1.045	-0.08
Recording a video or taking pictures of humiliating situations by cell phone	Victim	1.05	0.27	1.06	0.36	-0.356	-0.03
	Perpetrator	1.02	0.21	1.07	0.41	-1.650	-0.15

	Perpetrator	1.36	0.87	1.28	0.80	-.977	0.09
Repeatedly receiving or sending messages with threats, are intimidating by Skype, Facebook, etc.	Victim	1.12	0.53	1.11	0.48	0.206	0.01
	Perpetrator	1.04	0.33	1.08	0.48	-1.025	-0.09

*p<.05.

Same-Sex and Cross-Sex Cyberbullying

One of the least explored aspects of cyberbullying is gender differences when it addresses peers of the same sex, or the opposite sex. Accordingly, research into traditional bullying has reported that bullying between pre-adolescents and adolescents occurs mainly among members of the same sex, with aggression that affects members of the opposite sex obtaining very low prevalence rates (Wei & Jonson-Reid, 2011). However, when bullying addresses members of the opposite sex, there is data which indicates that females use more physical aggression against males (when we compare what males do to females). On the contrary, males employ more forms of verbal and social aggression when they address bullying to females (Navarro, Yubero, Larrañaga, & Macorison, 2012; Russell & Owens, 1999).

As far as we know, studying these gender differences in cyberbullying has not been the object of systematic analyses. The characteristics of cyberspace (e.g., the possibility that perpetrators remain anonymous) make their analysis difficult because it is possible that the victim is unaware of the perpetrator's gender. Nevertheless, previous research has indicated that the majority of cyberbullying occurs in groups of friends (Jackson, Cassidy, & Brown,

2013) and, in many other cases, cyberbullying is a reaction to an incident that has taken place at school (Cassidy, Jackson, & Brown, 2009), so perpetrators and victims of cyberbullying can know each other. Perpetrators in cyberbullying can also inform researchers about their victims' gender, but we know that the answer to this question is conditioned by the social desirability and sincerity of those who participate in a study of this kind.

If we take the results found in traditional bullying as a starting point, we might expect cyberbullying among people of the opposite sex to be less usual than among people of the same sex. Of the very few studies that have analysed these differences, Fenaughty and Harré's (2013) research in New Zealand (pupils aged 12-19 years) explored electronic harassment on the Internet and cell phones. These authors found that, as expected, males were significantly more likely to being victimised by other males over the phone and the Internet, whereas females were more to likely receive harassment by females in the two examined forms.

Nonetheless, when we consider previous results relating to traditional bullying, and the fact that one description of cyberbullying is that it is a new form of relational and social bullying (Beran & Li, 2008), the percentage of males who resort to cyberbullying against females is possibly higher than that of females who use it against males. To verify this premise, in one of the studies conducted in Spain (Navarro, Ruiz-Oliva, Larrañaga, & Yubero, 2015), we asked the participants to indicate not only if they had been victims or perpetrators of cyberbullying, but also the gender of their perpetrators or victims. The study sample included 1,058 children (516 females and 542 males, mean age = 11.08, SD = 0.80). Of these, 495 students (46.8%) were in year 5 and 563 were in year 6. Table 3 provides the data of those who indicated that they were victims of cyberbullying - in accordance with the gender of their perpetrators. We can see that most victims did not know their perpetrator's gender. No significant differences were found between males and females for those participants who knew their perpetrator's gender (χ^2 (d.f.:1) = 7.04, $p = 0.70$). Yet the data indicate that cyberbullying was perpetrated mainly by people of the same sex as the victim, and the number of participants who reported having suffered cyberbullying started by males and females is striking. It is feasible that this last result relates to the fact that while one person starts cyberbullying, others can help spread it over the Internet, or even participate in it, because it becomes a public event to which they can access (Smith, 2012).

Table 3. Gender differences in victims' prevalence according to unknown, male or female perpetrators

Participants' gender	Non victims	Victims who did not know their perpetrator's gender	Victims of males	Victims of females	Victims of males and females
Females	457 (88.6%)	35 (6.8%)	3 (0.6%)	9 (1.7%)	12 (2.3%)
Males	480 (88.6%)	37 (6.8%)	8 (1.5%)	2 (0.4%)	15 (2.7%)
Total	937	72	11	11	27

All of the perpetrators informed that they knew the gender of the person to whom they directed cyberbullying (see Table 4). Cyberbullying addressed significantly more people of the same sex than of the opposite sex. Yet if we compare the cyberbullying that the males and females indicated, more males reported getting involved in a form of cyberbullying that simultaneously addressed males and females (χ^2 (d.f.:1) = 12.93; $p < .005$).

Table 4. Gender differences in perpetrators' prevalence according to the gender of the target

Participants' gender	Non perpetrators	Perpetrator against males	Perpetrator against females	Perpetrator against males and females
Females	498 (96.5%)	1 (0.2%)	12 (2.3%)	5 (1.0%)
Males	520 (95.9%)	8 (1.5%)	3 (0.6%)	11 (2.0%)
Total	1,018	9	15	16

In general terms, the data indicate that most forms of cyberbullying address peers of the same sex. Yet despite the prevalence found being low, the percentages obtained seem to indicate that female victimization by males is less frequent than male victimization by females. This result supports former research which has indicated that males employ more forms of indirect and relational aggression when harassing females (Russell & Owens, 1999). The anonymity that the Internet offers may contribute to higher rates of bullying directed to females. This fact can be explained by the fact that, in comparison to the “real world,” males in virtual settings are less exposed to social condemning of aggression against females and to the “masculine gentlemanliness” norms that should guide male behaviour (Yubero & Navarro, 2006). In any case, we must reinforce research on this aspect of cyberbullying in order to reach valid conclusions.

However, different studies have documented that aggression between genders exists, which relates to matters such as sexual relationships, and they also represent one gender having more power over the other (e.g., Dunne, Humphreys, & Leach, 2006; Leach & Humphreys, 2007). Thus, gender identity development plays a key role in the development of hostile and antisocial behavior in adolescence, which often comes in the form of bullying. Duncan (1999) concludes that this form of aggression may be related with the initiation of heterosexual contacts and has a lot to do with social and school popularity because insults, in particular, go against adolescents' socio-sexual behavior. In this way, when both genders approach the opposite sex, searching for a dating relationship, popularity, leadership or peer's acceptance can favour the use of aggression. In line with this, Lahelma (2002) concluded that in the cases in which such behavior types shift toward intimidation, participants employ aggression as a form of social control to maintain hierarchical limits between genders, or to approach the opposite sex using conduct that can take the form of sexual harassment. So, if bullying takes the form of sexual harassment, research indicates that boys are more likely to be perpetrators, and girls are more likely to be victims (Duncan, 2004).

Therefore, sexual status and reputation are a central aspect of the social development of secondary education students. We believe that this dynamic is most important to understand the influence of gender socialisation, and to identify aggressive conduct that relates to certain “sexual hostility” among adolescents that can represent the threshold of other behaviours like homophobia or partner violence.

Despite former research showing that violent conduct can emerge in adolescence in romantic relationships (Díaz-Aguado & Martínez, 2014; Niolon et al., 2015), we have paid very little attention to analysing cyberbullying in such relationships. Although many victims do not know their perpetrators, other studies have demonstrated many adolescents' exposure to the

cyberbullying that former friends, classmates, and even boy- and girlfriends, or ex-boy/girlfriends, practice (Fenaughty & Harré, 2013). A recent study revealed that cyberbullying performed by someone with whom the victim has had some form of offline relationship causes even more unease for those suffering it because the former relationship could make harassment seem more intense and personal, and could involve more negative interactions (Mitchell, Ybarra, Jones, & Espelage, 2014).

For this reason, it is important to study romantic relationships because the information and communication technologies in this life stage are an important element to start and maintain intimate relationships (Korchmaros, Ybarra, & Mitchell, 2015), and could be a means by which to assault and control partners (Burke, Wallen, Vail-Smith, & Knox, 2011). Therefore, this subject requires further analysis since previous research has demonstrated that females tend to reject using violence to a greater extent, whereas males tend to justify and approve using violence against their partners. Moreover, many males minimise gender violence and even consider that the victims who receive violence are partly to blame for the situation they find themselves in (González-Ortega, Echeburúa, & Corral, 2008; O’Keefe, 2005). Indeed, more tolerant beliefs in, and attitudes to, violence against females is one of the risk factors for partner violence to occur. There are two very important risk conditions: (i) the tendency to justify and reproduce the sexist and violent models with which they have observed in their infancy and adolescence; (ii) the imbalance of power between males and females, which is the basis to create and perpetuate gender-linked stereotypes (González-Ortega et al., 2008; O’Keefe, 1998). Hence, research into cyberbullying must analyse to what extent it is practiced in romantic relationships, which gender is more exposed to aggression, and the specific forms it takes.

Students’ Perceptions of Gender and Cyberbullying

Researchers like Doucette (2013) have expressed the need to adopt a qualitative methodology if we wish to be sure about the role gender plays when analysing the implication of males and females in cyberbullying. More and more qualitative studies appear which analyse primary and secondary education students’ perception of cyberbullying (Kota, Schoohs, Benson, & Moreno, 2014; Misha, Saini, Solomon, 2009). Yet, as far as we know, none of these studies has specifically examined their perception of gender differences. Our goal in this section was to obtain as much information as possible from youths in elementary and secondary schools about their views of cyberbullying as a gender specific-behaviour. This information was obtained from focus groups that we formed to obtain in-depth views of cyberbullying in Spain. The work of Navarro and Sema (2016) describes the method, participants and procedures used. Table 5 shows the themes and subthemes, per gender and grade, to emerge from the discussion which took place in the focus groups, and quotations to illustrate youths’ views.

Generally speaking, most participants believed that cyberbullying is a conduct that can involve both genders, and as both perpetrators and victims. When they talked about victims, no specific aspects or characteristics appeared which can make males and females more vulnerable when suffering cyberbullying. Yet when they talked about perpetrators, they used arguments that remind us of the results obtained in research into traditional bullying. On the one hand, part of the participants of both genders see cyberbullying as a more typical strategy of females, as it allows people to cause harm without face to face confrontation and, in many cases, it involves

spreading secrets about other people or matters that have something to do with intimate aspects of their lives. In many cases, participants in the focus groups justify females' greater involvement using stereotyped beliefs that describe females as being more sibylline, harmful and vengeful than males. Not only males who participated in the discussion groups held on to such beliefs, but also some of the female participants did. Here it is important to consider that despite these results apparently coinciding with the studies which state that cyberbullying is a conduct in which more females get involved, as it may be an efficient means for indirect and relational aggression (Cassidy et al., 2009), young participants' opinions may not be based on real facts, but on the different gender stereotyped behaviour of males and females persisting.

On the other hand, part of the participants of both genders described cyberbullying as a problem of males - as they are normally more aggressive than females, so they would employ any aggression strategy to a greater extent than females, including cyberbullying. In these cases, however, cyberbullying is a way for people to introduce themselves assertively to others and to display certain masculine values associated with aggressiveness, arrogance and power. Cyberbullying performed by males is viewed as a continuation of traditional direct bullying, and even complements previous physical damage caused (e.g., break some of the victim's belongings or a fight). We can relate these results with other studies that have demonstrated how both traditional bullying and cyberbullying reinforce feelings of power and control among males and how, in these cases, bullying and cyberbullying can be an efficient power strategy to manage hierarchies in peer groups (Law, Shapka, Hymel, Olson, & Waterhouse, 2012).

In relation to this matter, secondary education students talk about the different reasons that can guide the cyberbullying performed by males and females. This theme did not appear in the primary education pupil groups. Popularity and leadership seem to be important reasons for both genders. So, participants' opinions showed different perspectives. On the one hand, there are people who could be less popular in peer groups at school and employ cyberbullying to get at those who are popular and to counteract the harassment they may suffer at school. On the other hand, some participants stated that people who are actually popular use cyberbullying to reinforce their position in the group as a continuation of events that take place at school. These perceptions coincide with previous research which has indicated that people resort to traditional bullying as a way to manage social status in peer groups (Guerra, Williams, & Sadek, 2011). Nevertheless, these motives seem to be more sensitive among females. Some of the female participants expressed that female's bullying behaviours are often driven by matters related with popularity, but also jealousy of, and rivalry with other peers. Females describe males as using motivations to guide them which, although related with power and status in a peer group, are more trivial, such as conflicts while practicing sports which they have not solved in person. Likewise, females are seen as more jealous, complex and envious than males, even when both genders employ cyberbullying as a way to manage their relationships in peer groups.

Table 5. Students' perceptions of gender differences in cyberbullying

Categories	Subcategories	Examples	Grade	Gender
Prevalence of cyberbullying	No differences per gender	<i>"Both boys and girls can insult you on their cell phone, or sometimes on the Internet. All they want to do is annoy you" an 11-year-old boy.</i>	Primary Secondary	Males Females
	Females get more involved as perpetrators	<i>"This is something more girls do because they are nastier. Girls tend to judge girls more, and boys don't judge so much or face people more than girls do. A girl doesn't easily ignore what others have done to her, so she can use it to get her own back or because she envies someone" A 14-year-old girl.</i>	Primary Secondary	Males Females
	Males get more involved as perpetrators	<i>"I think it's something more boys do because they're more aggressive. When they clash with someone, they hit them, and the same happens on the Internet . . . if a boy wants his friends to think he's tough, he can also do this on the Internet and he doesn't always need to be fighting" A 14-year-old girl.</i>	Primary Secondary	Males Females
Reasons for cyberbullying	Popularity, jealousy and envy among females.	<i>"I've seen two cases . . . one girl sees how her boyfriend receives photos of another girl who wants to go out with him. Rather than being angry with her boyfriend, she's jealous and starts saying awful things about the other girl on Facebook, then they fight when they meet. The other case is Z, the prettiest girl in class, and everyone gets at her on Facebook and Instagram because they so jealous that she's so pretty and all the boys are after her." A 15-year-old girl.</i>	Secondary	Males Females
	Popularity and former conflicts among males.	<i>"It's normal that there has been some clash before among boys. They might be playing football, or whatever, and when a foul is made against someone, they get at that person and run them down on Tuenti. Normally they sort things out, a bit of a fight, but nothing much." A 13-year-old boy.</i>	Secondary	Males Females
Forms of cyberbullying	Methods of attack	<i>"What I've seen is that girls upload more photos of other girls to laugh at them. As they were friends before and were always taking photos . . . when something happens, they upload photos of them when they don't look good or are doing something really silly to hurt them" A 12-year-old girl.</i> <i>"Girls are more subtle and have more ill-feelings than boys. We are rougher, but girls use more insults or things they know will really hurt another girl . . . they think about things more" A 13-year-old boy.</i>	Primary Secondary	Males Females

Table 5. (Continued)

Categories	Subcategories	Examples	Grade	Gender
	Differences in content of aggression	<i>“Girls write differently because they spell better and they write in a softer tone. Although they try to be aggressive, they don’t manage it enough. A boy makes more spelling mistakes, uses stronger words and more direct threats” A 13-year-old girl.</i>	Primary Secondary	Males Females
		<i>“Girls insult the way people look because they know it’s more annoying. If someone tells me I’m ugly and silly, telling me I’m ugly affects me more than them telling me I’m silly.” A 14-year-old girl.</i> <i>“It’s OK for a boy to sleep with lots of girls, but if a girl does this with lots of boys, watch out. Then the girl is a slut, but the boy is tough, and you can find these girls on the Internet shown to be “easy-to-get” or they even do it for small amount of money. When it comes to sex, girls lose out, and many boys upload photos of the girls who they have been with and comment about them.” A 15-year-old girl.</i>		

There were no major differences in the method of attack that males and females employ in cyberbullying, but many participants believe that the information that females upload on the Internet is more subtle, and entails them being better at planning their conduct, while males are more impulsive and post the first thing that comes to mind. They believe that the cyberbullying that involves posting photos in which people do not look good or are doing something silly is more characteristic of females, especially if this aggressive action addresses former friends because they have shared more time with their victims and have more material to use against them. They state that it is easy to distinguish if perpetrators are female because they are more careful when writing and spelling, insults are more intelligent and threats are more ambiguous. Yet almost all the groups agree when they say that females suffer more from the cyberbullying with sexual content that includes insults and rumours about someone’s sexual reputation or images of people in the nude and that, in most cases, males perpetrate this, although some females also do this.

Overall, the discourse of the target group participants indicates that both genders can get involved in cyberbullying as a victim or perpetrator, and there are different reasons that lead them to be perpetrators. However, we are concerned about a certain stereotype view that tends to predominate among Spanish (male and female) students who describe females as being much worse, more subtle, and more harmful than males. This demonstrates that the internalization of stereotyped beliefs that empirical research has shown are false (Artz et al., 2013). These results indicate that we must pay more attention to how youths employ internalized gender schemata to talk about aggression. Therefore, gender is an important factor not only for considering if

there are differences between the involvement of males and females in aggressive conduct or not, but also because we must consider its impact on the way it affects males and females' reasons for their aggression, and how these schemata may bias research.

CONCLUSION

We now go on to present the fundamental ideas that this review has led to. Readers should know that:

- 1) Most of the studies conducted to date have attempted to uncover the personal and social factors that make youths more vulnerable to suffering or perpetrating cyberbullying.
- 2) Gender forms part of the factors studied in most research studies on cyberbullying.
- 3) Gender is a social construct that defines what is masculine and feminine, and indicates how males and females should behave.
- 4) The Social Learning Theory states that socialisation processes allow us to acquire gender schemata, and that modelling by observation and imitation is a leading characteristic in these processes.
- 5) Research proposes that gender socialisation can affect differences in aggressive conduct, specifically learning instrumental (masculine) and expressive (feminine) traits.
- 6) Gender socialisation might indicate, for males, that aggression can prove useful for maintaining their gender role and, for females, that aggression can be inhibited or they can use more indirect forms of aggression, which better match their gender stereotype.
- 7) In traditional bullying, research tends to demonstrate that males get more involved than females. For many years, the common perception was that females used relational aggression to a greater extent, but recent research indicates that we cannot maintain this pattern today.
- 8) On occasion, although studies have provided mixed results, the general trend in cyberbullying conduct confirms that males are more aggressive than females, but differences in victimization are not significant.
- 9) Studies indicate that females are more often victims of cyberbullying rather than traditional bullying.
- 10) The data generally demonstrate that cyberbullying mostly targets peers of the same sex; however, there seems to be evidence that males direct more cyberbullying to females when compared to females using it against males.
- 11) Different studies have shown that many adolescents face cyberbullying that former friends perform, ex-classmates, but also by boy/girlfriends, or ex-boy/girlfriends. So cyberbullying may be a way to control and harass partners.
- 12) Gender stereotypes and roles are relevant factors when analysing how males and females reason about aggression and how they interpret behaviours like cyberbullying.

Chapter 140

RE-THINKING WELL-BEING MEASURES IN BULLYING AND CYBERBULLYING RESEARCH

Jolanta Burke* and Stephen James Minton

School of Education, Trinity College Dublin, Dublin, Republic of Ireland

INTRODUCTION

Both the impact of bullying and cyberbullying, and the knowledge that exists regarding the psychological make-up of those involved in bully/victim problems, have almost exclusively been measured in terms of deficits. Furthermore, and similarly, most of the research that focusses on both well-being and health, has been expressed in terms of measurements of the absence of ill-being and ill-health respectively, rather than the presence of well-being and positive health. This chapter provides an alternative view, in that it invites the reader to consider how we can conceptualise and measure well-being and health, and presents tools that can be used in the measurement of well-being that have been developed within the field of positive psychology. Accordingly, the concepts of Subjective Well-Being, Psychological Well-Being, the Authentic Happiness Model, the Well-Being Theory, the Dual Continua Model of Health, and the Mental Health Spectrum are presented, and tools used in the measurement of their attendant constructs are discussed. Given the modest levels of success recorded by many existing anti-bullying intervention programmes, we encourage you to consider the measurement of well-being in their ongoing attempts to inform the development of efficacious anti-bullying and anti-cyberbullying strategies.

BULLYING AND CYBERBULLYING

As Minton (2010, 2012) argues, most experts acknowledge the relevance of a number of key aspects in approaching a definition of bullying behaviour (as distinct from other, related forms of aggressive behaviour - see Olweus, 2003). Bullying behaviour is generally seen as

* Corresponding Author's Email: jburke4@tcd.ie.

being characterised by being (i) aggressive (verbally, psychologically, or physically); (ii) deliberate on the part of the perpetrator(s); (iii) generally unprovoked on the part of the target(s) of the bullying; (iv) repeated, or systematic in nature; and, (v) characterised by an imbalance of (physical, social, or technological) power in favour of the perpetrator(s) (Minton, 2010, 2012). Cyberbullying is typically characterized by similar criteria, although the technological medium of the aggressive behaviour is specified (e.g., Smith et al., 2006). However, Vandebosch, Van Cleemput, Mortelmans, and Walrave (2006) argue that there are important differences between cyberbullying and non-cyber forms of bullying: “With cyberbullying, it is not necessarily the case that the victim is harassed repeatedly. A defamatory website, for example, will often stay online for a longer period of time and can, moreover, be read by many individuals. A spoken insult, by contrast, disappears from the moment it is uttered, and is only heard by those present at the time” (p. 1).

As O’Moore and Minton (2011) point out, this line of argument prompts those who would seek to provide definitions of bullying and cyberbullying to consider “. . . where the ‘repetition’ lies; in cyberbullying, the perpetrator’s act of posting offensive material is a one-off event, but due to the possibility of multiple viewers and viewing, the target’s experience of being abused is one of repetition” (p. 4). As Minton (2010, 2012) argues, such a distinction prompts educationalists and policy-makers to think about how they respond to bullying. Indeed, in the most recent guidelines provided to primary and post-primary schools in Ireland in forming anti-bullying policies and strategies (Department of Education and Skills, 2013), such a distinction is evident in how schools are advised to respond to different types of cyberbullying. The Anti-Bullying Procedures for Primary and Post-Primary Schools state that whilst “. . . placing a once-off offensive or hurtful public message, image or statement on a social network site or other public forum where that message, image or statement can be viewed and / or repeated by other people will be regarded as bullying behaviour.” This is in keeping with Vandebosch et al.’s idea (2006) that given the “. . . possibility of multiple viewers and viewing, the target’s experience of being abused is one of repetition” (p. 1). However, the Department of Education (2013) go on to say that “. . . isolated or once-off incidents of intentional negative behaviour, including a once-off offensive or hurtful text message or other private messaging do not fall within this definition of bullying and should be dealt with, as appropriate, in accordance with the school’s code of behaviour” So the notion of repetition (whether that be of perpetrator activity in face-to-face bullying, or target experience in cyberbullying) is key; according to governmental guidelines on anti-bullying policies for schools in Ireland, posting offensive text on, for example, Facebook is cyberbullying, but posting the same offensive text in a once-only private text message is not.

The consequences of bullying and cyberbullying have been extensively examined, and range from decreases in academic performance and psychological health (Kowalski & Limber, 2013), through to developing psychosomatic difficulties such as sleeping problems, headaches, poor appetite (Beckman, Hagqvist, & Hellström, 2012) and an increase of suicidal behaviour (Hinduja & Patchin, 2010; Kessel Schneider, O’Donnell, Stueve, & Coulter, 2012; Klomek, Marrocco, Kleinman, Schonfeld, & Gould, 2008). Olweus’ pioneering work on bully/victim problems showed that those bullied at school had higher levels of depression and poorer self-esteem in adulthood (see Olweus, 1993), and O’Moore and Minton (2004) recorded that being made the target of bullying behaviour can, and often does, “. . . destroy a person’s confidence and self-esteem [and] cause physical, emotional and psychological damage of the potentially most serious and long-lasting kind.” In Finland, Kaltiala-Heino (1999) found that having been

bullied was associated with depression and suicidal ideation; this finding was replicated by Roland (2000) in a study of a representative sample of 2,083 eighth graders (approximately 14 years old) in Norwegian schools. In a study of 209 12 to 15 year old bullied and non-bullied students (97 male, 112 female) in eight urban post-primary schools in Ireland, Mills, Guerin, Lynch, Daly, and Fitzpatrick (2004) found that having been bullied was significantly linked to depression, suicidal ideation, having made a suicide attempt, and referral to psychiatric services. In a study in Finland of 423 parents and 420 children, Kumpulainen, Räsänen, and Puura (2001), using diagnostic measures based on those used in Michael Rutter's classic studies of psychiatric epidemiology amongst children on the Isle of Wight (1964-1974), which included survey items on bullying (Rutter 1976), found that children involved in bully/victim problems were more prone to have psychiatric disorders than non-involved children, with the most common diagnoses among children involved in bully/victim problems being attention deficit disorder, oppositional/conduct disorder, and depression.

What researchers have found about the personalities and psychological make-up of those involved in bullying behaviour has also been dominated by findings concerning the correlation between involvement in bully/victim problems and the preponderance of negative patterns of behaviour and personality traits. For example, those who bully have been found to be proactively aggressive, and those who are targeted to be reactively aggressive (Roland & Idsøe, 2001; Salmivalli & Nieminen, 2002); links have been found between poor student self-esteem and involvement in bullying behaviour in schools (O'Moore & Kirkham, 2001); and trait psychopathy has been found to predict the perpetration of cyber-aggression amongst adolescents (Pabian, De Backer & Vandebosch, 2015).

It is, of course, entirely understandable and proportionate that researchers have illuminated the negative consequences of involvement in bullying behaviour. Similarly, it is understandable that researchers have focused - at least thus far - on the negative traits typical of those involved in perpetrating what is surely universally held to be an anti-social and undesirable pattern of behaviour. Even when the apparently "positive" construct of emotional intelligence has been investigated by bullying researchers, it was found to be negatively correlated (in terms of the regulation of emotions) with involvement in the perpetration of traditional bullying and cyberbullying (Baroncelli & Ciucci, 2014). However, in this chapter, it is our intention to buck this general trend somewhat, in presenting an alternative development; that is to say, in focusing on variances in the positive psychological attribute of *well-being* amongst those involved in the various aspects of bullying and cyberbullying behaviour.

HOW WE CAN CONCEPTUALISE AND MEASURE WELL-BEING

Whilst there is disagreement amongst researchers as to which well-being theory best reflects well-being, researchers in the area have generally encouraged a multi-faceted approach to measuring the construct (Forgeard, Jayawickreme, Kern, & Seligman, 2011; Ryff & Singer, 1998). The theories that have been developed regarding well-being emphasise a potentially broad array of components that constitute and influence well-being. In the absence of consensus, therefore, the list of constituting and influencing components that have been offered thus far cannot be seen as exhaustive; furthermore, whilst some of the components have been found to overlap, others have not. Hence, depending on the research questions that have been

broached, various approaches can and have been used in the understanding and measurement of well-being.

There has been, however, a greater level of agreement regarding possible methods of the measurement of well-being. Generally speaking, modes of measurement have followed the approach that is common to hierarchical models (of personality traits, and intelligence) that are familiar from the psychology of individual differences. Hence, measures of well-being have been constructed to permit the measurement of the individual levels of their assumed sub-components; hence, the outcomes of these measures offer an “overall” well-being score, which comprises the sum of their assumed sub-componential scores, which can also be offered. Conceptually, therefore, in order to increase overall well-being, it is assumed that each sub-component can be increased, and that the sum of those increases will have an impact on overall well-being. Moneta (2014) has referred to this approach as a “body-builder” approach to measuring well-being, and has argued that more research needs to be carried out to investigate whether it is possible for individuals to achieve the highest levels of scoring on all components of a well-being model, as well as whether it is beneficial for individuals to aim to do so.

To step back a little, it is of importance to note that two main philosophical traditions have been identified as impacting upon and informing research into the psychology of well-being, namely *hedonia* and *eudaimonia* (Ryan & Deci, 2001). *Hedonia* (from the Greek ἡδονισμός [hedonismos], “delight,” which is in turn, from ἡδονή (hēdonē), “pleasure”) was developed by Aristippus of Cyrene, a student of Socrates, who developed the principle that pleasure is the beginning and goal of a happy life. *Eudaimonia* (from the Greek, εὐδαιμονία [eudaimonía], “happiness,” “welfare,” or “human flourishing”), on the other hand, was proposed by Aristotle who claimed that the hedonic approach to happiness was vulgar (Irwin, 1999) and described eudaimonia as a state of being well, by living in accordance with the virtues (Ackrill, 1975). Psychological theories that have been formulated subsequently have generally either reflected hedonic or eudaimonic understandings of well-being. Whilst some psychological understandings of well-being have attempted to reflect both approaches, Ryan and Deci (2001) assert that from the eudaimonic perspective, such an integration is impossible, as an emphasis on individualistic pleasure-seeking (hedonia) cannot be equated with the eudaimonic emphasis on living by collectivistic virtues.

Subjective Well-Being (SWB) theory, for example, derives from the hedonic philosophical tradition, and asserts the existence and operation of three inter-related components: life satisfaction, pleasant affect, and unpleasant affect (Diener & Suh, 1997). Life satisfaction, which is seen as the cognitive element of the theory, is held to be the individual's perception and evaluation of the discrepancy between his or her present situation, and what he or she believes his or her ideal life should be. The affective elements of the theory measures the individual's experience of both positive and negative emotions (Diener, Suh, Lucas, & Smith, 1999). Empirically, the three components have been found to be correlated, but separate constructs (Diener, Smith, & Fujita, 1995; Lucas, Diener, & Suh, 1996). The components have shown fair temporal stability over four- (Headey & Wearing, 1992), and seven-year periods (Magnus, Diener, Fujita, & Pavot, 1993); consequently, SWB has been presented as being a trait-like variable. Accordingly, many scales have been developed with the express purpose of measuring SWB. Most are based on self-report, and these include the *Satisfaction with Life Scale* (SWLF: Diener, Emmons, Larsen, & Griffin, 1984); the *Temporal Satisfaction with Life Scale* (TSLS: Pavot, Diener, & Suh, 1998); the *Subjective Happiness Scale* (SHS: Lyubomirsky & Lepper, 1999), and *The Oxford Happiness Questionnaire* (OHQ: Hills & Argyle, 2002).

There are also many scales available that measure positive and negative affect, rather than negative affect only; these include the *Positive and Negative Affect Schedule* (PANAS: Watson, Clark & Tellegen, 1988), and the *Scale of Positive and Negative Experiences* (SPANE: Diener et al., 2009). Apart from self-report, experience sampling methods have been employed by, and found useful in, measuring subjective well-being (Stone, Schiffman, DeVries, & Frijters, 1999). However, Diener (2000) has pointed out that subjective well-being is, by definition, a measure of 'subjective' experience, and therefore care should be taken not to attempt to objectify it.

Psychological Well-Being (PWB) theory, on the other hand, reflects the eudaimonic tradition, and asserts the existence and operation of five elements: self-acceptance, positive relations, autonomy, environmental mastery, purpose in life, and personal growth (Ryff & Keyes, 1995). This is a theory-driven model which acknowledges the heritage of decades of psychological research. In particular, the theories of Erikson (1959), Maslow (1968) and Rogers (1963) are held by Ryff and Keyes (1995) as influential. PWB theory aims to address a rather fundamental question - that is to say, what it means to be "psychologically well." According to the PWB theory, individuals who achieve high levels in each one of the components will become a fully-functioning, or to borrow from Maslow, as Ryff and Keyes (1995) do, a self-actualising, person. Curiously, for a model that posits itself as drawing on phenomenological psychology, the theory disregards affective aspects of well-being, and psychometric modes of measurement have been advocated. For example, in order to measure psychological well-being, Ryff (1989) developed a Psychological Well-Being Scale (PWBS), which is a 20-item scale, with shorter versions available for researchers to use (14, 9, and 3-item).

Despite Ryan and Deci's (2001) reservations regarding attempts at such integrations, the *Authentic Happiness Model* attempts to combine hedonic and eudaimonic elements of well-being (Seligman, 2003). The three components of the theory are the life of pleasure, engagement, and meaning, which represent routes to happiness. Conceptually, the life of pleasure is, of course, informed by the ethos of the hedonic tradition; it is a study of aspects of life that make it pleasant and unpleasant (Kahneman, Diener, & Schwarz, 1999). The life of engagement describes the experiences of psychological flow, which allows individuals to function at their fullest capacity (Csikszentmihalyi, 2009). Finally, the life of meaning draws on the eudaimonia tradition, and describes pursuits of virtues (Seligman, 2003). The first attempts to measure Authentic Happiness were made via the construction and the application of the *Steen Happiness Index* (SHI: Seligman, Steen, Park, & Peterson, 2005), which was subsequently adapted in the construction of the Authentic Happiness Inventory (AHI: Peterson, 2005). At present, there is limited empirical data about the validity and reliability of the AHI. The questionnaire that is now most commonly used to measure three dimensions of authentic happiness is the *Orientations to Happiness Questionnaire* (OHQ: Peterson, Park & Seligman, 2005), which has been tested in multiple languages; a shorter version of the OHQ is now available to researchers (Ruch, Martínez-Martí, Heintz, & Brouwers, 2014). Seligman (2011) is also responsible for the creation of the *Well-Being Theory*, in which *well-being* is said to consist of five components: positive emotions, engagement, relationships, meaning, and accomplishment. Three components have been adopted from the authentic happiness theory (positive emotions, engagement, and meaning), and two new components have been created (relationships and accomplishment). The anagram of the components is PERMA, and therefore it is often referred to as a PERMA model. Well-Being Theory has been measured with the

newly-created PERMA profiler (Butler & Kern, unpublished), which is a 23-item scale that has been tested on a sample of over ten thousand respondents.

HOW WE CAN CONCEPTUALISE AND MEASURE HEALTH

According to the World Health Organization, health is defined as “a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity” (WHO, 1948). Therefore, in order to measure well-being, positive states of well-being need to be measured, not only the absence of negative states. Over fifty years ago, Jahoda (1958) argued that the absence of mental illness and the presence of mental health are two distinct variables. Herzlich (1973) agreed, adding that individuals might not become aware of health until illness affects it; however, not experiencing illness, does not constitute health. For decades, little progress has been made to find empirical evidence for the distinction between mental illness and health, until Ryff and Singer (1998) proposed to revisit this issue and prompted scientific debate about its merits (e.g., Diener, Sapyta, Suh, 1998; Fleury, 1998; Ito & Cacioppo, 1998), as well as instigated a surge of further research in the area.

From the affective viewpoint, there is research to support the idea that positive affect is *not* simply the opposite of negative affect - i.e., positive feelings are not merely the absence of negative ones, or negative mental health. Indeed, it has been found that positive affect and negative affect may be only modestly negatively correlated (Cacioppo & Bernston, 1999; Headey, 2006). Furthermore, Huppert and Whittington (2003) found that ill-being and well-being can exist concurrently within individuals. In a longitudinal study, with 6,317 respondents from the UK, positive well-being and negative well-being were compared. It was found that 35.1% of respondents reported high scores on the existence of psychiatric conditions and similarly high scores on experiences of positive well-being, or low scores in both positive and negative well-being. If positive and negative well-being were merely opposites, participants' scores would consistently show a simultaneous reduction in negative well-being and an increase in positive well-being, or vice versa. This suggests, we feel, that it may prove useful to measure positive well-being and negative well-being as related, but separate, constructs.

The *Dual Continua Model of Health* was the first model that introduced the concept of *flourishing*. Flourishing is defined as the pinnacle of mental health, wherein individuals “. . . thrive, prosper and fare well in endeavours” (Michalec, Keyes, & Nalkur, 2009, p. 393). Following on from this concept, *languishing* was introduced as a state between well-being and ill-being. Individuals scoring low on 6 of 11 scales of positive functioning. In a large scale study, Keyes (2002) found that the risk of depression was twice as likely among individuals experiencing languishing than it was amongst those who were moderately mentally healthy. Furthermore, the risk was six times greater among languishing than flourishing participants. Therefore, Keyes (2002) speculated that languishing may be as debilitating as depression. The Dual Continua Model of Health utilises a diagnostic tool that classifies three sets of mental health symptoms: psychological well-being (PWB: Ryff & Keyes, 1995), social well-being (SWB: Keyes, 1998), and emotional well-being (EWB: Diener, 2000).

The *Mental Health Spectrum* is a model of flourishing that consists of two components: the first one incorporates a set of three core features, and the second one six additional features. The core set of features are based on the Authentic Happiness model (see above), and include

positive emotions, engagement, and meaning. The additional features incorporate self-esteem, optimism, resilience, vitality, self-determination, and positive relationships. It is an approach that promotes a population-level, rather than individual-level approach to improving well-being (Huppert, 2009). Huppert posits that there are considerably more individuals in each society who are moderately healthy and only a small proportion of those experiencing mental illness and languishing. Therefore, focusing on moving the moderately healthy individuals into the flourishing state may have a significant effect on reducing the prevalence of mental disorders.

The mental health spectrum was measured in a large sample study across 23 European countries (Huppert & So, 2013). The scale used to measure well-being was a 54-item

European Social Survey (ESS) which compared the common mental health disorders such as depression and anxiety with indicators of well-being (Huppert et al., 2009). The results have shown that the ten features of positive mental health functioning included: competence, emotional stability, engagement, meaning, optimism, positive emotion, positive relationship, resilience, self-esteem, and vitality. These features represent both eudaimonic and hedonic elements, as well as components of the previously mentioned PERMA model. To date, these elements offer the basis of the most comprehensive conceptual framework of well-being.

THE ADVANTAGES OF THINKING ABOUT WELL-BEING AND POSITIVE HEALTH IN ANTI-BULLYING RESEARCH

As we noted in the early part of this chapter, well-being in bullying and cyberbullying literature has, predominantly, been measured in terms of absence of illness, such as symptoms of depression and anxiety (e.g., Clark et al., 2014; Greenleaf, Petrie, & Martin, 2014; Kaltiala-Heino, 1999; Kowalski & Limber, 2013; Rivers & Noret, 2008; Turner, Reynolds, Lee, Subasic, & Bromhead, 2014; Young & Sweeting, 2004), psychiatric conditions (Kumpulainen et al., 2001; Mc Guckin, Lewis, & Cummins, 2010; Mills et al., 1994; Young & Sweeting, 2004), self-harm behaviours (Bucchianeri et al., 2014; Hinduja & Patchin, 2010; Ozdemir & Stattin, 2011), or psychosomatic symptoms (Beckman et al., 2012; Sourander et al., 2010). However, this dichotomous approach to well-being assumes that the school population may be divided into students with or without psychiatric conditions, such as affective disorders, and that those involved in bullying and cyberbullying may be displaying symptoms of mental illness (and conversely, lack of mental illness is assumed to indicate mental health). Furthermore, in the well-meaning attempt to illustrate the serious impact that bullying and cyberbullying behaviour can have, the borrowing from psychiatric and psychological diagnostic understandings can obscure the fact that at least some, if not the majority, of the upset that is experienced and expressed by bullied individuals is entirely proportionate to their being the recipient of unfair, unwanted and undeserved aggressive treatment, rather than being indicative of internalised pathological symptomatology. Feeling afraid, despondent and isolated as a result of ongoing bullying is entirely understandable - most people who have been bullied feel this way, and this is due to their having been treated badly, rather than their being in any way psychiatrically ill. And yet were these people to fill in psychometric inventories of, say, depression or anxiety at the time, the results of those psychometric tests could indicate otherwise.

As we have already suggested, there are, of course, other important implications for applying a purely deficit approach to the measurement of well-being and health. In the first-place, face validity is reduced, as deficit-based scales measure either the presence or the lack of ill-being and ill-health, and not the presence of well-being and positive health. As an example, it would, therefore, be invalid to conclude that being a target of bullying behaviour *necessarily* reduces feelings of positive well-being, if one was to draw on evidence derived from a measurement that points (and critically, by design, *can only point*) to an increase in ill-being. Secondly, crucial information could be missed if the measurement of bullying behaviour were to be incorrectly applied, as demonstrated in two studies carried out by Huppert and Whittington. After analysing data, Huppert and Whittington (1995) deduced that symptoms of psychological distress predicted mortality in a seven-year longitudinal study. When data was revisited using four sub-scales which differentiated between positively and negatively worded responses, Whittington and Huppert (1998) found that mortality was correlated with the absence of life satisfaction and enjoyment, rather than the presence of anxiety or depression. Therefore, not only can distinguishing well-being and ill-being, and positive health and ill-health, provide additional findings when studying bullying and cyberbullying, but more importantly, it may prevent the researchers from making incorrect inferences.

As yet, there are very few studies within the bullying and cyberbullying literature that have utilised measures of well-being, rather than the absence of ill-being. However, Drennan, Brown, and Mort (2011) used a *Satisfaction with Life Scale* measure (Pavot & Diener, 1993) to measure the impact of telephone bullying on adolescents. Smithyman, Fireman, and Asher (2014) used a *Brief Multi-Dimensional Student Life Satisfaction Scale* (BMSLSS: Huebner, Suldo, Valois, Drane, & Zullig, 2004), in order to identify long-term consequences of peer victimisation. Goswami (2012) used single-item scales (Cantril, 1965; Cummins & Lau, 2005) in order to explore the correlation between subjective well-being and bullying. The use of well-being scales is innovative in the above studies. However, care needs to be taken as to what type of scales are used to measure well-being. For example, the single-item scales in Goswami's (2012) research, which measured evaluation of well-being, is subject to retrospective thinking. Kahneman and Riis (2007) posit that questions such as: "What's your happiness with life as a whole?" involve the participants' evaluation of life, a cognitive task that is conceptually distinct from the lived experience of well-being. Moreover, positive and negative affect, of course, impact on the evaluation of past experiences (Redelmeier & Kahneman, 1996), and therefore, the single-item scale may prove insufficient to measure subjective well-being.

Again, as we have already noted, considering the real-life and serious impact that the experience of having been bullied or cyberbullied can have, and indeed has had, upon many people, it is understandable that the research literature has focused on the negative impact such behaviours experienced by participants, with aims to design interventions to reduce bullying and cyberbullying. With an eye towards the development of efficacious intervention strategies, there could be, however, merits in measuring well-being as one of the constructs. In the first place, such a measurement would allow researchers to understand the extent of the consequences of bullying and cyberbullying more broadly (more broadly, that is, than reference being made only to deficit-based measures). Secondly, a person's overall psychological response to involvement in bullying or cyberbullying may be somewhat complex, and will certainly vary. For example, bully/victims (those involved in bullying behaviour as both perpetrators and targets) have been found to display more internalising problems than have bullies or victims (Ozdemir & Statin, 2011). Measuring well-being may help researchers

identify the necessary complexities in this domain. Farrington and Ttofi's (2009) meta-analysis of 44 anti-bullying programmes conducted between 1983 and 2009 showed that school-based programmes succeeded in reducing reports of having bullied others by between 20% and 23%, and having been bullied by between 17% and 20%. Furthermore, Merrell et al.'s (2008) meta-analysis of anti-bullying intervention research conducted between 1980 and 2004 indicated that programmes are more likely to influence knowledge, attitudes and self-perceptions concerning bullying, than they are actual bullying behaviours. Indeed, in Norway, traditionally a world leader in anti-bullying research and intervention, in a report commissioned by the Norwegian Directorate for Education and Training, Lødding and Vibe (2010) stated that "... bullying is not a problem that can be solved by adopting a specific programme ... features of a good learning environment can help reduce bullying" (p. 26). Whilst the logic of Lødding and Vibe's (2010) argument has been criticised (Minton, 2014; Olweus & Breivik, 2011), the uncomfortable fact remains that the success that anti-bullying intervention programmes have had is actually been rather modest (Minton, 2014). If we are to continue to advocate that anti-bullying intervention strategies and interventions be evidence-based (and it is difficult to see what else could be argued), then surely it makes sense to broaden that evidence basis beyond the paths that we have already trodden. The measurement of attributes such as well-being in bullying and cyberbullying research could be a useful first step towards the generation of potentially more effective interventions in our future anti-bullying and anti-cyberbullying intervention strategies.

CONCLUSION

This chapter presented the approaches to the measurement well-being in the context of positive psychology. The main theories of well-being have been discussed as an alternative to the prevalent measurements of the absence of ill-being in the current bullying and cyberbullying literature. The approaches and models presented above constitute an innovative approach to the measurement of well-being. Rather than continue to focus solely on identifying the absence of ill-being, as is prevalent in the current bullying and cyberbullying literature, we would like to encourage researchers to consider the measurement of well-being in their attempts to improve the efficacy of anti-bullying and anti-cyberbullying intervention strategies.

Chapter 141

PHYSICAL PROXIMITY, SOCIAL DISTANCE AND CYBERBULLYING RESEARCH

Stephen James Minton*

School of Education, Trinity College Dublin, Dublin, Ireland

INTRODUCTION

In this chapter, the idea of *distance* (be that literal/physical, or psychological (e.g., social, or moral)) is examined, with specific reference to its potential importance in understanding cyberbullying. A critical review of the general trends in cyberbullying research is then undertaken, and the potential advantages of placing a greater emphasis on qualitative research in the future, which might facilitate the elicitation of young people's own meaning-making in acts of cyber-aggression, are examined.

PROXIMITY AND AGGRESSIVE BEHAVIOUR

The notion of *distance* (both *physical proximity*, and so-called “*social distance*”) as a factor in understanding aggressive and prejudicial behaviour has had a lengthy history in research in the social sciences (e.g., Bogardus, 1926, 1947; Karakayali, 2009; Matthews & Matlock, 2011), but has not, in my opinion, received sufficient attention in the area of cyberbullying to date. As cyberbullying can be seen as systematic aggression at a distance afforded by technology, the factors of physical proximity and social distancing would seem to be particularly pertinent. Even after the passing of half a century, as a direct laboratory demonstration of the effects of variations in *physical proximity* on the likelihood of a person delivering noxious stimuli, the results of the variations in the set-up of the famous (and some might say, infamous) experimental demonstrations of conformity to authority by Stanley Milgram (1965) are still significant. It may be recalled by the reader that the genesis of the original series of experiments was interesting; as a young man, Milgram had seen the films of the results of the Nuremberg

* Corresponding Author's Email: mintonst@tcd.ie.

trials, at which many Nazi officer and soldier defendants attempted to evade their responsibility for their crimes, on the basis of having simply “followed orders.” The experiments began at Yale University in July 1961, three months after the start of the trial of Adolph Eichman in Jerusalem. An unfortunate outcome of the publication of the results of the Nuremberg trials, regarding folk psychology understandings amongst the populations of the victorious Allies, had been the development of the view that somehow, “Germans were different” and that, “the same thing couldn’t happen here.” According to Milgram, these were dangerous falsehoods, and in the original series of experiments he demonstrated that psychologically “normal” American people could, and in fact did, reject or ignore their own feelings of sympathy or empathy for an apparently suffering and dying fellow human being in favour of showing obedience to the authority of an experimenter (Milgram, 1965).¹ The subsequent variations of the original set-up (reported by Milgram, 1974), altered the physical proximity between the “teacher,” “learner,” and experimenter. Compliance (in terms of the “teacher” “completing” the study; that is to say, continuing to the maximum voltage) decreased with increasing distance between the experimenter and the “teacher” - when the “teacher” received telephone instructions from the experimenter, rather than being in the same room, compliance decreased to 21 per cent. Gender had no impact on “teacher” compliancy. The original set-up had involved male participants between 20 and 50 years of age; when an all-female sample of teachers were used, obedience levels were not significantly different, although the female participants were more likely to report experiencing higher levels of stress. Most significantly of all for the current discussion, the series of variant demonstrations showed that *physical proximity was found to predict the levels of compliance amongst the genuine participants*. For example, in a situation where proximity was at a maximum, the participants had to physically hold the learner's arm onto a shock plate, and compliance decreased to 30 per cent. Conversely, where proximity was at a minimum, and participants had to perform a subsidiary task such as reading the questions to the learner, or logging the answers of the learners, with a “teacher” (in this case, a stooge) complying fully, 37 out of 40 participants completed the study (a compliance rate of 92.5 per cent) (see Milgram, 1974).

¹ The original demonstration (Milgram, 1965) involved participants, who had been paid a fee of \$4 (plus 50 cents car fare) for one hour's participation in “a study of memory and learning,” being duped into believing that they were delivering, via an electroshock generating machine, shocks of increasing severity to a fellow participant (to whom they were introduced at the beginning of the procedure) in a “learner” role in the room next door, according to the learners’ “errors” in a “word-association learning task.” The genuine participants’ apparently “random” assignment to the “teacher” role was fixed; the learners were in fact “stooges,” that is to say, actor confederates of the experimenter; and the “shock generating equipment” was bogus. The teachers were instructed to give the learners a “shock” each time that the learner made a mistake. The shocks were to increase by 15 volts each time; the “shock machine” had levers up to “450 volts,” followed by three more levers marked by large X’s and “Danger.” At 120 volts, the teacher would hear the learner complain of pain; at 210 volts, the teacher would hear the learner complain of a “heart condition”, and make repeated requests to be able to get out of the room; and after 330 volts, there was only an ominous silence. On hesitation, the genuine participant received prompts from the experimenter; in order, these were (i) “please continue”; (ii) the experiment requires that you continue; (iii) it is absolutely essential that you continue; and (iv) you have no other choice, you must go on (see Milgram, 1965, 1974). Before conducting the experiment, Milgram had undertaken polls at Yale, asking 14 final-year undergraduate psychology students, and 40 psychiatrists from the medical school, asking them to predict what proportion of teachers would go “all the way” to the maximum voltage. Those polled predicted that only a pathological few of the teachers (estimations amongst the psychology undergraduates ranged from 0 to 3 per cent, and amongst the psychiatrists was around 10 per cent) would do so. Such predictions amongst those polled fell well short; in Milgram's first set of demonstrations, 26 out of 40 teachers - that is to say, 65 per cent - continued up to and including the maximum voltage (Milgram, 1965, 1974).

The relationships between the lack of physical proximity to our own weapons, the consequent rise in the destructive capability of those weapons, and our simultaneous shirking of responsibility for the effect of those weapons on others and ourselves was elucidated by “the father of modern ethology,” Konrad Zacharias Lorenz. In what many consider to be his masterpiece, “*Das sogenannte Böse*” (1963; first translated into English under the title, “*On Aggression*” in 1966), Lorenz, took as his subject matter “...the fighting instinct in beast and man which is directed against members of the same species” (Lorenz, 1966, p. ix) - hence, intra-specific “fighting,” rather than the usually predator-prey, or defensive, inter-specific aggression. Intra-specific fighting almost always - in non-human animal species - confers a survival advantage at the species level, despite the apparent risk to the individuals involved in the confrontation. Lorenz (1953, 1966) provided numerous examples of how, whenever an animal species develops a “weapon” (which grows on its own body) such as a fang, claw, or horn, which could potentially inflict serious or fatal injury, that species invariably develops a social inhibition to prevent the usage of that weapon, otherwise the survival of the species as a whole would be placed under threat. Hence, fighting in animal species becomes heavily ritualised - a series of posturing challenges and threats, and dominance and appeasement gestures. The relationship between the evolutionary development of weapons of animal species, and of social inhibitions against their use is particularly important when we come to “...the one being in possession of weapons which do not grow on his body and of whose working plan, therefore, the instincts of his species know nothing and in the usage of which he has no correspondingly adequate inhibition. That being is man” (Lorenz, 1953, p. 216–217).

According to Lorenz, it is our differential progression as a species that has sealed our potential for self-destruction - the pace at which we have developed our weapons technology has far outstripped the progress we have made in treating our fellow beings ethically and humanely (1953): “...with unarrested growth his [man’s] weapons increase in monstrosity ... But innate impulses and inhibitions, like bodily structures, need time for their development ... We did not receive our weapons from nature. We made them ourselves, of our own free will ... The day will come when two warring factions will be faced with the possibility of wiping the other out completely” (p. 217).

SOCIAL DISTANCE, AGGRESSIVE BEHAVIOUR AND CYBERBULLYING

The “distancing” of ourselves from our weapons, and the responsibility for the destructive effects of our aggression, is not only maintained through *decreased physical proximity*, but also *increasing social distance*. The mechanisation of physical genocide, as observed in the gas chambers and crematoria of Auschwitz, was based on *both* factors. Survivors of the concentration camps, some of the psychology of which Milgram (1965, 1974) had attempted to understand through laboratory demonstrations as a peace-time researcher, have testified in the bleakest possible way the role of *decreased physical proximity* at critical moments, in making mass killing possible. The Austrian psychiatrist, and later founder of *logotherapy*, Viktor Frankl's first-hand witness experience as a prisoner of Auschwitz, for example, tells of how the Zyklon B capsules that delivered the poisonous gas to the chambers were not positioned in the delivery hatches by the SS soldiers themselves, but rather by a special detail of prisoners, whose refusal to comply would have led to them taking the place of their fellow

prisoners in the chambers (Frankl, 1985). Furthermore, in understanding the psychology of the death camps, many researchers have pointed to the role of *increasing social distance*. Frankl (1985) and another Auschwitz survivor, the Italian chemist Primo Levi (2006), recorded that prisoners of the Nazis were not referred to as prisoners, or in any person-related way; when talking about prisoners, Nazi soldiers would invariably use the multi-purpose, but usually object-related, German word *Stück* (translated literally, “piece”) instead. The Nazis were able to do what they did to the prisoners of the camps because many of those prisoners were not considered (and this, of course, had legal underpinnings in the Nuremberg Laws) human at all. Philip Zimbardo has reflected that in times of war, soldiers and even civilian populations on opposite sides of a conflict come to use collectivising, derogatory, and dehumanising language to refer to one another (Zimbardo, 2007). Numerous examples, throughout history, exist of the use of dehumanising language in which “enemy” populations, and particularly the *children* of “enemy” populations, are referred to in *verminous* terms. Colonel John Chivington, a former Methodist missionary and a then-candidate for Congress, who led “...a special volunteer unit of voluntary cavalry [that had been] raised for the expressed purpose of “exterminating” all Cheyennes and Arapahos residing within territorial boundaries” (Churchill, 2003, p. 53), resulting in the massacre of almost 600 Indians at the Cheyenne-Arapaho village at a bend at Sand Creek in 1864, said that his policy was to “...kill and scalp all [Indians], little and big,” advocating the wholesale slaughter of the Indian children as “*nits make lice*” (Stannard, 1992, p. 131, *italics mine*). Stannard (1992) also pointed out that half a century later, Heinrich Himmler described the extermination of Jewry as “*delousing*” and that at the time of the Iraq war, Iraqi soldiers were referred to as “*cockroaches*” by US soldiers, a term also used to describe the Tutsi minority and Hutu moderates during the 1994 Rwanda genocide (Herbert; in Selby, 2015). On Monday, 7th July 2014, Israeli politician Ayelet Shaked, a representative of the far-right Jewish Home party, said of the Israeli-Palestinian conflict on her Facebook page that: “Behind every terrorist stand dozens of men and women, without whom he could not engage in terrorism. They are all enemy combatants ... this also includes the mothers of the martyrs ... They should follow their sons, nothing would be more just. They should go, as should the physical homes in which they raised the *snakes*. Otherwise, more *little snakes* will be raised there (cited in Hillel, 2014).²

As well as dehumanising the “other,” or “enemy” populations, social distancing achieves, often simultaneously, another function in establishing and embellishing One-Other relationships - the de-individuation of the “one.” The “bystander effect,” also known as “bystander apathy,” and “social loafing,” is often explained by the fact that in uncertain situations, the initial response of human beings is to look for what *others* are doing, and then to behave in a similar way (Latané, 1981). From the mid-1960s, Latané and Darley investigated what became known as the “bystander effect,” or “bystander apathy” - why people fail to intervene and to help in emergency situations. In a typical experiment, participants in a “waiting room” would see smoke pouring over the top of the laboratory door, or perhaps hear a female

² In 2015, Katie Hopkins, a columnist with the British gutter-press tabloid newspaper *The Sun*, and her editor David Dinsmore were reported to the London’s Metropolitan Police by D. Peter Herbert, the Chair of the Society of Black Lawyers, for incitement to racial hatred, following Hopkins’ description, once again as “cockroaches”, of desperate migrants who had drowned in the Mediterranean (Selby, 2015). Whether Hopkins, who used the language employed, as we have seen, by active participants in genocides in the United States, Nazi-occupied Europe, Rwanda, and Israel saw or sees those desperate migrants as an “enemy population” is not clear; however, as Suzanne Moore (2015) noted, Hopkins’ use of such language demonstrated that “...on immigration, the language of genocide has entered the mainstream.”

scream, or a crash from behind the door. The factors which determined whether the participants attempted to intervene were the presence of others (the more people in the proximity, the less likely they were to intervene) and ambiguity or otherwise of the situation (the more clearly the situation appeared to be an emergency, the more likely they were to act). When an individual is “one-of-many,” his own sense of *social responsibility* becomes “diffuse” (Latané, 1981), as he or she “deindividuates.” This has also been used to explain why some people behave anti-socially, as the sense of anonymity within the crowd disinhibits impulsive anti-social behaviours (Latané, 1981). We have already seen in the laboratory demonstrations of Stanley Milgram (1965, 1974) that our sense of personal responsibility, at least in as far as we may measure its behavioural correlates, appears to be diminished further when we are directly told or ordered to do something by a person in “authority” - when someone else “is in charge,” then we can tell ourselves that we are simply “following orders.”

In the rigid military hierarchy of Nazi Germany, the route of buck-passing was a clear one; but what of other situations of genocide? From which “authorities” did those involved in the genocide against the native peoples of the New World receive their orders? For one, the federal Indian agents and US Army officers who were involved in the negotiations of treaties with the Indians in the latter half of the nineteenth century often referred to the “Great Father” in the East, who, according to whatever best suited the white men’s points, was either full of love for or full of anger with his “red children” (see Brown, 1970). However, there was a more powerful authority still, who apparently commanded the obedient whole-scale slaughter and destruction of the Indians by the immigrants from the Old World and their descendants – God Almighty himself. The historian David Stannard (1992) argued that the four hundred year conquest of the New World was an extended series of Holy Wars mounted by the European colonists, and that the difference in the specific modalities of the genocidal activities in North and Central/South America is explainable via the temporal, and above all, denominational differences between the Anglo-American settlers and Spanish *conquistadors*. In the medieval Spanish/Roman Catholic mindset, the tradition of *contemptus mundi* (“contempt for the world,” which by the fourteenth century had developed into the practices of self-flagellation, self-starvation, and a variety of other forms of corporal mortifications), coupled with the unquestioned widespread beliefs in witchcraft and Satanic practices, and the Papally-approved hunt for, torture, and killing of heretics by the Inquisition, led to the simultaneous fascination with, and acclaimed horror of, the sexual becoming devolved onto the uncivilised, non-Christian, non-European races. Within European tradition, of course, and back to the time of Ancient Greece, slavery provided an economically sound alternative use of non-persons (as slaves were under Roman law) (Stannard, 1992). In contrast, the Calvinist and Puritanical British settlers of North America, according to Stannard (1992), reasoned that “...those without a sense of private property were, by definition, not putting their land to “good or profitable use” and “...therefore, they deserved to be dispossessed of it” (p. 234). The Spanish were hungry for the mineral wealth that could be extracted from the land, and so economically, needed (at least some of) the native people of Central and South America as slaves; the British were hungry for the land itself, and therefore had no use for the native people of North America, who were an economic obstacle to their territorial ambitions. As Stannard (1992) concluded, “... allegedly having shown themselves to be beyond conversion to Christian and civil life – and with little British or American need for them as slaves – straightforward mass killing of the Indians was deemed the only thing to do.” (p. 247).

The language used by the European settlers involved in the western expansion of the United States of the nineteenth century did not reflect the physical and cultural genocide committed against the Indian, or the theft of his land. The key provision of the 1834 Act of the United States Congress (*An Act to Regulate Trade and Intercourse with the Indian Tribes and to Preserve Peace on the Frontiers*), which determined that all land west of the Mississippi, excluding that within the states of Missouri and Louisiana and the territory of Arkansas, would be Indian country, thus establishing a so-called “permanent frontier” (Brown, 1970; Churchill, 2003) was already nonsensical by 1860, with statehood being granted to California, Colorado and Minnesota, and the growth of the Kansas and Nebraska territories, in the 1850s. The proximal separation between the European-American and the Indian tribes was to be a short-lived strategy, and instead: “To justify these breaches of the “permanent Indian frontier,” “the policy makers in Washington invented “Manifest Destiny,” a term which lifted land hunger to a lofty plane. The Europeans and their descendants were ordained by destiny to rule all of America. They were the dominant race and therefore responsible for the Indians – along with their lands, their forests, and their mineral wealth. Only the New Englanders, who had destroyed or driven out their Indians, spoke out against “Manifest Destiny” (Brown, 1970, p. 8).

More famously, perhaps, those involved in the twentieth century genocide committed against the Jewish people by the Nazis included similar mystifying language, again with the express purpose of deindividuating the One responsible, and transforming mass slaughter and greed for property and land into a “higher purpose.” Among other precautions, in order to keep the “secret”, in official language only cautious and cynical euphemisms were employed: one did not write “exterminations”, but instead, “final solution”; not “deportation”, but instead, “transfer”; not “killing by gas”, but instead, “special treatment”; and so on (Levi, 2006, p. 384).

As we have seen, then, we attempt to morally distance ourselves from our own behaviour, and the social consequences of that behaviour, by employing the tactics of distance in two other modalities - *decreased physical proximity*, and *increased social distance*. When we utilise the latter in order to make justifications of aggressive behaviour, we do so via dehumanisation of the Other, and deindividuation of the One, thus diffusing our own feelings of responsibility. As well as these *post hoc* interpretations, we may also predict that if (i) we do not share physical proximity with another person; and/or (ii) we socially distance ourselves from another person, such that we have no feelings of empathy with that other person, then we will be able to disregard our own agency in terms of our subsequent responsibility for our negative behaviour towards that other person. In short, it will be more likely for us to behave aggressively towards a person we do not have to share space with, or face, or a person whom we have effectively marginalised from the concerns of the One that we belong to, and easier for us to live with the consequences.

The bullying of someone else by technological means - mobile telephones, games systems, online social networks - like other forms of bullying, is understood as a form of aggressive behaviour (see Smith et al., 2006, and discussion below), but unlike other forms of bullying behaviour, permits the perpetrator to attack the target from a remote location, and therefore outside of a face-to-face context. If we follow the Lorenzian (1953) reasoning outlined above, we may get to the suppositions that (i) we may find it easier to kill someone with a weapon that is not of our body (say, to shoot him with a rifle) than it is to beat him to death; and (ii) we may find it “easier” to enter the system code that triggers a missile launch resulting in our wiping out the existence of tens of thousands of unknown, faceless people than it is to (say) hack ten

individuals to death with an axe, being that this latter sort of attack would mean that we had to stand toe-to-toe and face-to-face with our opponents. If what has been said about *physical proximity* (and to a lesser extent, *social distancing*, which is possible, although perhaps not as likely, in face-to-face forms of bullying) has relevance to the phenomenon of *cyberbullying* - and of course, I would argue that it does - then we might expect that it is “easier” in terms of the availability of *post hoc* self-justifications, and our living with the consequences, to attack and bully someone on-line, than it is to attack and bully that person in a face-to-face situation.

Pornari and Wood’s (2010) quantitative research provided some interesting headway into the idea of whether social distancing can have an effect, in terms of its provision of an investigation of “...cognitive mechanisms, applied by people to rationalise and justify harmful acts, and engagement in traditional peer and cyber aggression among school children” (p. 81). Amongst their sample of 339 secondary school children, cyber aggression was positively related to moral disengagement and moral justification. Traditional (that is, non-cyber-) peer aggression was positively related to children’s moral justification, euphemistic language, displacement of responsibility, and outcome expectancies, and negatively associated with hostile attribution bias. Traditional peer aggression and cyber aggression were also highly associated. Pornari and Wood (2010) concluded that their data had indicated “...the need for future research to elaborate on the current findings, in order to advance theory and inform existing and future school interventions tackling aggression and bullying” (p. 81). However, whilst their work into differential contribution of cognitive mechanisms is an important contribution as regards understanding social distancing, much of the quantitative research that exists, and continues to be undertaken, into bullying and cyberbullying research is focused on the establishment of incidence rates and typologies or the outcome of intervention programmes - utilising self-report participant questionnaires which rest on the assumption of concordance between participant understandings and researcher definitions. To understand what sense young people may make for themselves of aggressive behaviour in the technological sphere, and even to answer the apparently simple, theoretically obvious, and yet seemingly undressed issue of whether remote location makes a difference, I would argue for a re-thinking of what research methodologies might be most helpful.

THE CASE FOR DIVERSE APPROACHES IN CYBER-BULLYING RESEARCH

If I may be permitted a personal reflection, my own involvement in conducting empirical research into cyberbullying has been neither lengthy, nor extensive. In 2007, I was asked to present a paper to the Psychological Society of Ireland’s Special Interest Group in Child and Adolescent Psychology, with the title, “*What do we know about Cyber-Bullying?*” (Minton, 2007a). Only half-jokingly, the first slide that I used in that presentation was entitled, “The Short Answer,” and the body of text on the slide was limited to two words: “Not enough!”. At this point, I was able to offer various media accounts of youth suicide linked to cyberbullying; a definition and sub-typology of cyberbullying, from Peter Smith et al.’s (2006) report of their study of 92 11-16 year-olds in London. Indeed, Smith, Mahdavi, Carvalho, and Tippet’s (2006) data, along with Qing Li’s (2006) study of 177 seventh-graders in Canadian schools, formed much of the basis for what I could offer regarding evidence on (especially) online

cyberbullying. The empirical evidence that I could draw on from Ireland was slim indeed; apart from data gleaned from a single item on bullying via mobile telephones that had been included in the questionnaire that I had used in my own Ph.D. research (Minton, 2007b) (“Other pupils have sent nasty text messages to me, or used mobile phones to get at me” to which 2,312 primary school and 3,257 post-primary school pupils had responded), quite simply, there was nothing there. Small wonder that I concluded that presentation with the note that, “The evidence we have is essentially either small-scale, anecdotal, or provisional. This is neither empirically nor – in terms of adhering to evidence-based practice – professionally satisfactory. Hence, large-scale study is desirable. Such a project is due to start in October” (2007a).

It was, in fact, thirteen months, rather than six months, later (so May 2008) by the time that I had successfully arranged the necessary funding (from RTÉ [*Radio Telfios Éireann*: the national broadcaster] and the *Irish Independent* newspaper) to conduct a large-scale study of cyberbullying in Ireland, which involved 2,794 12-16 year-olds from eight post-primary schools completing a 38-item questionnaire (see O’Moore & Minton, 2009, 2011). This contribution from Ireland seemed to be part of what was an explosion of interest in the area of cyberbullying, as other chapters in this book will surely have documented. Indeed, by the time that I presented a research paper at the 2011 *European Conference on Developmental Psychology* in Bergen, Norway (Minton, 2011), no less a person than Dan Olweus gave a special pre-conference presentation on the issue of cyberbullying. Olweus’ contribution was an interesting one: he posited that although substantial media and research attention was being given to cyberbullying, that it was in fact an over-estimated and actually a quite low-prevalence phenomenon (see Olweus, 2012). Nevertheless, of the papers that addressed bullying that were presented at that particular conference, over one-third were on the subject of cyberbullying.

Cyberbullying research often received input - especially in its earliest days - from those who had already achieved international expert status in the area of research of school bullying, e.g., Peter Smith (see Smith et al., 2006), Justin Patchin (see Patchin & Hinduja, 2006), and Mona O’Moore (see O’Moore & Minton, 2009 (I too had cut my teeth in the area of school bullying before approaching cyberbullying, but I make no claim to international expert status myself). There appears to have been an assumption on the part of these researchers that cyberbullying was a directly analogous phenomenon to school bullying; that what had been happening in the school yards down the centuries was now being played out on mobile telephones, or over the Internet - that the bullying had “spread online.” In order to illustrate this, let us first consider a widely used definition of bullying behaviour: “A person is bullied when he or she is exposed, repeatedly and over time, to negative actions on the part of one or more other persons, and he or she has difficulty defending himself or herself” (Olweus, 1993, p. 14).

Now, let us consider the definition of cyberbullying presented by Smith et al., (2006), and used by them (and also Mona O’Moore and myself) in our early studies on cyberbullying (O’Moore & Minton, 2009, 2011; Smith et al., 2006): “Cyberbullying is an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly over time against a victim who cannot easily defend him- or herself” (Smith et al., 2006).

Smith et al.’s (2006) definition of cyberbullying shares the characteristics of Olweus’ most definition of bullying behaviour (i.e., that it is [i] aggressive; [ii] intentional on the part of the perpetrator(s); [iii] repeated, or systematic in nature; and, [iv] characterised by an imbalance of power, in favour of the perpetrator(s) [see also Minton, 2010, 2012]), adding to this understanding a modality, i.e., the use of “electronic forms of contact.” Since the systematic

research of bullying behaviour began, self-report questionnaires have specified a definition of bullying for the respondents, and then assumed that having been so instructed in the definition of bullying, that the respondents' understanding of bullying was one and the same as that of those who designed the questionnaire. Indeed, we used Smith et al.'s (2006) definition of cyberbullying in the questionnaire that we designed specifically for our study of cyberbullying in Irish post-primary schools (O'Moore & Minton, 2009, 2011), and this approach is typical in self-report measures of cyberbullying, as well as those of bullying. So what has developed is that we, as researchers of cyberbullying have assumed that children and adolescents today understand instances of upsetting and aggressive behaviour that they experience and perpetrate on-line in the same way that we do, that is to say, as an extension of school yard bullying. However, there is no clear reason why they should share this type of understanding with us; indeed, there is rather more reason to suspect that such an assumption that they do share our understanding is an artefact of the way in which the cyberbullying research tradition has developed.

Indeed, empirical evidence collected in Ireland supports the idea that the way in which participants are instructed to categorise the aggressive behaviour that they have experienced or perpetrated online has an effect on the incidence rates that emerge. In a study of 2,474 Irish second-level school students (aged between 12 and 19 years), a definition of cyberbullying was provided, followed by a single questionnaire regarding perpetration, and a single questionnaire item regarding having been targeted. Using the frequency of "once a month or more often" 2.24 per cent of respondents indicated involvement as a target, and 1.12 per cent as a perpetrator of cyberbullying. However, when self-reported involvement in cyber aggression was recorded in the same sample (using two nine-item scales, one scale regarding perpetration, and one scale regarding having been targeted, again using the frequency of "once a month or more often"), with no definition of cyber aggression being provided, 10.83 per cent of respondents indicated involvement as a target, and 5.15 per cent as a perpetrator of cyber aggression (Corcoran, McGuckin, & Prentice, 2015). Olweus, amongst many others keen to define bullying properly, has demonstrated consistently that bullying is a narrowly confined form of aggression (see especially Olweus, 1993, 1999). Corcoran et al., (2015) have shown that in the digital environment, too, online, cyber aggression and the narrower cyberbullying are by no means interchangeable terms. This demonstrates something about the importance of researchers' understandings; indeed, the authors concluded that: "Rather than attempting to "shoe-horn" this abusive behaviour into the preconceived conceptual framework that provides an understanding of traditional bullying, it is timely to take an alternative approach . . . it is now time to turn our attention to the broader issue of cyber aggression, rather than persist with the narrow focus that is cyberbullying (p. 244).

I, too, would argue for a fresh approach, but perhaps of a different kind, as I feel that Corcoran et al.'s (2015) findings also support the assertion that young people's understandings could and should be given greater gravity in informing how researchers categorise online behaviour. This seems to me to be a better starting point than the assumption that aggression in the digital environment (which may well be a "new phenomenon" to established researchers in aggressive behaviour, but is a life-long reality to the so-called "digital native" participants involved in their studies) is necessarily directly comparable to the situation of the school yard (a familiar, and historical situation to researchers and young participants alike). Research into bullying behaviour, be that the establishment of incidence rates and typology, the study of demographic differences, or the assessment of the outcomes of anti-bullying intervention

programmes, has always been dominated by quantitative research (see Farrington & Ttofi, 2009; Smith, 2003; Smith et al., 1999). There are good social reasons for this. It is important for experts to be able to provide reliable answers to questions asked by legislators, policy makers, educators, and the general public regarding the scale of the problem of bullying, and questions from those who would financially support anti-bullying programmes about the effectiveness, or likely effectiveness, of such measures. Such an approach, however, presupposes either that young people share, or can/should be brought to share, the understandings of bullying behaviour already established (although often debated) by experts. To an extent, in the arena of schools, this is an ecologically valid approach, especially when it is applied to research into anti-bullying interventions, where such programmes rely, as they invariably do, on raising young people's awareness (and the awareness of adults in school communities) of what bullying is, and challenging bullying behaviour (Minton, 2014; for examples of anti-bullying programmes, see Minton, O'Mahoney, & Conway-Walsh, 2013; Olweus, 1997; O'Moore & Minton, 2005; Roland, Bru, Midthassel, & Vaaland, 2010; Salmivalli, Kärnä, & Poskiparta, 2011; and for reviews of anti-bullying programmes, see Farrington & Ttofi, 2009; Smith, 2003; Smith, Pepler & Rigby, 2004). However, the meaning-making actually employed by young people in their on-line activities remains elusive (if that meaning-making is not one and the same as that of the researchers) if we circumscribe this by either providing definitions of cyberbullying (to be shared - or ignored! - by our young participants) (e.g., Li, 2006; O'Moore & Minton, 2009, 2011; Patchin & Hinduja, 2006; Smith et al., 2006), or follow Corcoran et al.'s (2015) idea of focusing on the broader area of cyber aggression (an area that is still conceptually circumscribed by researcher understandings in the construction of self-report questionnaires, whether it is defined for participants on such inventories or not).

Participant meaning-making, in my opinion, might best be derived by the utilisation of qualitative methodologies (see also Hunter, Lusardi, Zucker, Jacelon & Chandler, 2002), which thus far have been (at least in terms of published output) only seldom applied to the areas of bullying and cyberbullying behaviour. Interestingly, in what is probably the most frequently cited example of qualitative research in cyberbullying, Vandebosch and Van Cleemput's (2008) participants' understandings of cyberbullying was found to match researcher definitions. Data derived from 53 focus groups (comprised of school students aged between 10 and 18 years), showed that the participants interpreted "cyber-bullying" as "Internet bullying" and in order for it to be considered "true" cyberbullying, the actions should (i) be intended by the perpetrator to be hurtful; (ii) be perceived by the target as hurtful; (iii) be part of a repetitive pattern of negative offline or online actions; and, (iv) be performed in a relationship characterised by a power imbalance (based on "real-life" power criteria, such as physical strength or age, and/or on ICT-related criteria such as technological know-how and anonymity). However, it is not necessarily the case that these findings reflect all young people's spontaneous understanding of cyberbullying. Despite the relatively (in this field) early vintage of this study, cyberbullying has long been part of the wider public consciousness in Belgium, where Vandebosch and Van Cleemput conducted their study, due in no small part to the success of the Nic Balthazar-directed 2007 film "Ben X" which depicts the cyberbullying of a boy with Asperger's syndrome, and was itself inspired by the real-life cyberbullying-related suicide of a 17-year old boy with autism in Belgium in 2002 (Nic Balthazar makes a film, 2005). Šleglova and Cerna's (2011) qualitative work, conducted via semi-structured interviews with fifteen 14- to 18-year-old targets of cyberbullying in the Czech Republic), was largely focused on the coping strategies used by their participants. It was found that whereas the participants, depending on

their experiences, might use technical defences, activity directed at the perpetrator, avoidance or utilise social support from peers, that some technical coping strategies were found to be ineffective, and the coping strategy most often recommended to young targets of bullying telling one's parents - was not used at all. Helen Johnson's (2012) work focused on teaching professionals rather than young people; she reported on a thematic analysis of semi-structured interviews with eight anti-bullying coordinators (employed in primary, secondary, middle and high school settings) in the UK, with results indicating that teaching professionals, and indeed schools, were beginning to develop an understanding of issues relating to cyberbullying, to acknowledge its unique features, and to develop a range of methods to counter and prevent cyberbullying; however, the schools were in need of additional support in order to be more comprehensive in their approaches.

We have seen, via Pornari and Wood's (2010) (quantitative) research, the link between the internal (cognitive) rationalisation and justification of harmful acts to the increased participation in the perpetration of bullying and cyberbullying amongst young people (see above). We have also seen that whilst Vandebosch and Van Cleemput's (2008) qualitative research (see above) showed that Belgian pre-teens and teenagers' understanding of cyberbullying matched with that of researchers in 2008, there is no firm reason to believe that that is still, or is more generally, the case - the area of young people's online and technological activity moves quickly, as many researchers of cyberbullying have commented in the past. As we have also seen, qualitative research has been rather under-utilised within cyberbullying research. It is my suggestion that in (i) the further exploration of the physical proximity/social distance/aggression issue, as applied to cyberbullying, and (ii) in the broader issue of understanding young people's meaning-making around cyberbullying and cyber aggression, that qualitative approaches could be appropriately and usefully employed, and that significant in-roads into these understandings could be made.

CONCLUSION

We have seen that, if illuminated through the lenses of classical ethology and classic social cognitive theory, it is reasonable to expect that the distance (both *physical proximity* and *social distancing*) has a relevance to the phenomenon of *cyberbullying*, in that it might be "easier" to attack and bully someone online than it is to attack and bully that person in a face-to-face situation. However, the testing of this idea has been obscured by the fact that the bulk of the cyberbullying research conducted to date has been quantitative in nature, conducted by those with a pre-existing expertise in face-to-face bullying who have assumed that cyberbullying is merely an online extension of face-to-face bullying, and that the young people involved in this phenomenon either share or, for the purposes of research, can be brought to share, the researchers' own understandings of cyberbullying. It is suggested that, especially given that there is no clear basis for making these assumptions, and the comparative "newness" of the field, that a greater emphasis on qualitative research in future might help to elicit young people's meaning-making regarding their online activities and use of technology.

Chapter 142

THE EU KIDS ONLINE PROJECT: THE IMPORTANCE OF LARGE SCALE CROSS-NATIONAL RESEARCH

Brian O'Neill* and Thuy Dinh

Dublin Institute of Technology, Dublin, Ireland

INTRODUCTION

Cyberbullying or the use of online or electronic forms of communication to harass, threaten, and otherwise inflict harm has become one of the most talked about negative consequences of young people's use of Internet technologies. With ever increasing and diversifying online platforms, policymakers have sometimes struggled to find the right balance to support youthful adoption of social media and the need for protection and/or redress when things go wrong. Crucially, policymakers require evidence to support decision making and to target solutions to problems that have sometimes been the subject of heightened public concern and anxiety.

Since 2007, EU Kids Online has sought to contribute on a pan-European basis a body of research and evidence regarding young people's experiences with Internet technologies. EU Kids Online is a multinational research network that seeks to enhance knowledge of European children's online opportunities, risks, and safety thereby lending greater understanding of the online landscape that increasingly frames children and young people's experiences. Through large scale survey research, EU Kids Online offers an insight into children's online lives across Europe and provides a baseline on which to assess trends in the situations that children find problematic. Uniquely, this project has, through its close relationship with the Safer Internet Programme of the European Commission, sought to contribute to policy debates as well as solutions and to play a role with other stakeholders on some of the key problematic issues affecting young people.

The harmful effects of bullying and harassment on children and young people have long been of concern to parents, educators, and policy makers, long before the Internet became such a feature of contemporary life. That the online world presents a new environment in which vulnerable children can be victimized and a space where perpetrators find new ways to perform acts of harassment has been acknowledged by educators and online safety experts as one of the most complex issues facing children's online participation. Yet, the extent to which this is a risk identified by children and the manner in which they respond to experiences of bullying and harassment remains a challenging research question. Bullying and online harassment feature as one of the risks asked about in the EU Kids Online survey, and while not the most prevalent of negative experiences that children describe, it is the one that was found to have the most severe impact. Key findings from EU Kids Online and the wider contribution of cross-national large scale studies to cyberbullying research are the subject of this chapter.

SAFER INTERNET RESEARCH IN CONTEXT

The rapidity with which the Internet has been embraced by young people and the speed at which it has impacted young people's approach to communication and access to information and entertainment is remarkable. Young people have been to the fore in embracing new Internet technologies (Rice & Haythornthwaite, 2006), adapting them effortlessly to new modes of social interaction (Boyd, 2008), and forging new and often unexpected opportunities for learning (Ito et al., 2008). Yet, a dual discourse counterpointing the diverse multiple opportunities that the Internet affords with attendant risks and concerns with how best to manage young people's engagement with a complex amalgam of technologically-mediated content and contact risks has preoccupied policy makers, almost since its inception (Gill, 1996).

The first phase of policy interventions towards dealing with potentially harmful effects of the Internet downsides may be said to have been largely founded on the assumed risks it posed to children, based variously on intelligence from industry, law enforcement, and child welfare experts supported by limited forms of research alongside political concerns regarding child protection. Much of this was framed at an international level with the EU and the US playing leading roles in framing the principal themes of risks and safety online (European Commission, 1996; Internet Safety Technical Task Force, 2008). The European Commission's Safer Internet Programme acted on a pan-European level to support efforts to combat illegal uses of the Internet, principally the use of Internet technologies to exploit children and disseminate child abuse images, and to raise awareness, especially among parents and educators of the risks, predominantly content-based, that the Internet might pose to young people (European Commission, 1999).

The rise of social media and the explosion of young people's active participation in online social networking gave the lie to this policy approach. Egregious as online child abuse or exploitation is, the framing of education and awareness approaches around risks of exposure to online predation appeared increasingly irrelevant to the real experiences, positive and negative, that young people encountered. The absence of an adequate evidence base to inform such policy led to the development of the EU Kids Online as a Europe-wide research network committed to producing reliable evidence of children's online opportunities, risks, and safety. Preceded by a number of international comparative studies such as the Safety Awareness, Facts and Tools

or SAFT survey (Staksrud, 2005), and a series of Eurobarometer studies on Internet safety (Eurobarometer, 2005, 2007), EU Kids Online was the first project to propose a robust and comparable, survey-based investigation of children's (and their parents') access and use of the Internet as well as approaches to dealing with problems encountered online.

EU Kids Online originated as a so-called "knowledge enhancement" project for the European Commission's Safer Internet Programme in order to support policy decision making processes related to online services used by young people. In its first phase (2006-09), EU Kids Online created a network of European researchers and a body of knowledge based on comparative analysis of the existing evidence base on children and online technologies conducted in Europe. A key contribution was its classification of the typology of *content*, *contact*, or *conduct* risks and opportunities that arise in the context of young people going online (Livingstone & Haddon, 2009). Going against the popular rhetoric of "digital natives" (Prensky, 2001), it was argued many children still lacked the resources to use the Internet sufficiently to explore its opportunities or to develop vital digital literacy skills (Helsper & Eynon, 2010), highlighting the importance of encouraging and facilitating children's confident and flexible Internet use.

An overriding priority was the need for reliable comparative data with which to assess the extent of the challenges facing young people in Europe when using the Internet. With 75% of European children regularly going online, many observers celebrated children's youthful expertise while others worried about their vulnerability to new forms of harm. Policies to balance the goals of maximising opportunities and minimising risks require an evidence based approach. Therefore, with funding from the EC Safer Internet Programme from 2009-11, EU Kids Online proceeded to design and conduct a major quantitative survey of 9-16 year olds experiences of online use, risk, and safety in 25 European countries (Livingstone, Haddon, Gorzig, & Ólafsson, 2011a). The underlying aim of the survey was to enhance knowledge of European children's and parents' experiences and practices regarding risky and safer use of the Internet and new online technologies in order to inform the promotion among national and international stakeholders of a safer online environment for children. The approach adopted was child-centred, comparative, critical, and contextual and informed by a socio-ecological perspective to better understand individual children's experiences within the diverse and varied contexts that constituted the wider European landscape (O'Neill, 2015).

THE EU KIDS ONLINE SURVEY

The EU Kids Online survey (2009-11) was a unique research endeavour in terms of breadth and scope of its investigation of online risks for children aged 9-16. A random stratified sample of 25,142 children aged 9-16 who used the Internet, plus one of their parents, was interviewed during Spring/Summer 2010 in 25 European countries. The survey investigated key online risks: pornography, bullying, receiving sexual messages, contact with people not known face-to-face, offline meetings with online contacts, potentially harmful user-generated content, and personal data misuse. Although a quantitative approach by theoretical and methodological design, the survey also collected free form responses to open-ended questions of what pre-occupied and bothered children on the Internet.

A number of features of the methodology for EU Kids Online stand out to distinguish it from earlier cross-national studies such as Eurobarometer. In the first instance, the research is child-centred and reports incidence based on accounts provided by children themselves. Both children and their parents were surveyed as part of the research but it is the child's account that is reported in cross-national analysis. Secondly, a robust methodology was used to ensure representativeness of the sample on the national level and standardisation of sampling methods to ensure appropriate comparability across all countries included in the study. Thirdly, every effort was taken to ensure the reliability of children's responses through an ethically-sensitive approach. Children were interviewed in their own homes by specially trained interviewers. Self-completion sections were included for sensitive questions, with care taken to ensure that children were enabled to provide responses to sensitive issues without any adult interference. An optional open-ended question was also included to allow children to describe any situation they had experienced in which they were made to feel uncomfortable or which had bothered them. The question path in the survey was one in which initially all children were asked about incidence of exposure to risks. For those who did experience any of the risks asked about, this was followed by questions which asked them about impact and how it had made them feel. This was then subsequently filtered such that only those who had been adversely affected were then asked what they had done about it or to whom they turned for help and support.

Previous research indicated that the patterns and social contexts of general Internet use are key factors shaping children's online activities and online risks encountered (Livingstone, Haddon, & Görzig, 2012). Online experience is defined as a pathway composed of the online activities engaged in by children and the online and offline factors (e.g., family, social and cultural environment) that shape children's behaviours toward the technological world. This approach, based on Bronfenbrenner's socio-ecological model, offers a re-conceptualization of the child's ecology as a multi-layered set of nested and interconnecting environmental systems, all of which influence the developing child but with varying degrees of directness (Bronfenbrenner, 1997). The perspective has evolved since its early inception and today acknowledges the role of the child's own characteristics, hence the model is now referred to as the bio-ecological model (Bronfenbrenner & Morris, 2006). The framework recognizes the complex interdependencies between the institutions and structures that support or constrain children's opportunities and their agency in making choices and decisions online while negotiating these possibilities and constraints. While limited demographic data was collected from parents to determine socio-economic status (SES), independent variables relating to national context were used to examine cross-country differences and are discussed further below (Lobe, Livingstone, Ólafsson, & Vobed, 2011).

Four main areas of risk were at the core of the investigation as set out by EU Kids Online: (i) exposure to sexual images online, (ii) sending and receiving sexual messages, (iii) bullying and harassment, and (iv) meeting strangers. The range of risks was selected based on a review of the available evidence derived from empirical studies that had been conducted across Europe (Hasebrink, Livingstone, & Haddon, 2008) and a classification of risks identified in the literature (Livingstone & Haddon, 2009). A typology of risks according to content, contact, and conduct was developed, recognising children as actors and participants as well as consumers of content, in need of protection (Table 1).

Table 1. EU Kids Online Classification of Risks

	Content Child as receiver (of mass productions)	Contact Child as participant (adult- initiated activity)	Conduct Child as actor (perpetrator/victim)
Aggressive	Violent / gory content	Harassment, stalking	Bullying, hostile peer activity
Sexual	Pornographic content	“Grooming”, sexual abuse or exploitation	Sexually harassment, “sexting”
Values	Racist / hateful content	Ideological persuasion	Potentially harmful user- generated content
Commercial	Embedded marketing	Personal data misuse	Gambling, copyright infringement

Figure 1. Relating online use, activities and risk factors to harm to children.

Much initial policy activity, as discussed above, was focused on content risks, drawing on well-established tropes of child protection in media contexts, seeking to provide “safer” forms of access for children to content in online, largely unregulated spaces. Accordingly, filtering tools were proposed as an important technology-enabled step towards restricting access to mass-produced content that may be unsuitable for children (Staksrud & Kirksæther, 2013). Children as participants in contact risks (adult-initiated) similarly is well-represented in the literature of online risks with children vulnerable to online predation (Gillespie, 2008), forms of ideological manipulation (Rogan, 2006), and online harassment by strangers (Peter, Valkenburg, & Schouten, 2006). Importantly, the typology recognises the increasingly active role of children in use of the Internet and in contexts in which they may be at risk of being the victim or even the instigator of acts that threaten or endanger others. It is in this context that

EU Kids Online has created a comprehensive evidence base across 25 countries in Europe regarding the incidence and response to bullying and other risks encountered through Internet technologies.

The EU Kids Online model explains adolescents' online risks and opportunities within a specifically adapted socio-ecological framework (Görzig & Machackova, 2015) (see Figure 1). Guided by this model, the EU Kids Online survey captured variables on the level of the individual as well as their parents, peers, and teachers. In addition, the survey data allows linkage with country level data, thus enabling the ability to capture the *cultural level* of the socio-ecological system by using country as a proxy.

In the following sections, we discuss findings relating to cyberbullying from the EU Kids Online survey and map the factors that emerged from the survey to the three distinct levels of the *individual*, the *family*, and the *country* level. Cyberbullying is usually defined as a form of bullying that uses electronic means such as email, mobile phone calls, text messages, instant messenger contact, photos, social networking sites, and personal web pages, with the intention of causing harm to another person through repeated hostile conduct. This can include forms of aggression such as humiliation, harassment, social exclusion, mockery, and unpleasant comments (Smith et al., 2008). In terms of the classification of risks above, cyberbullying is one of several conduct risks that may harm children through online contact with others. While a familiar term in English-speaking usage, "bullying" proved to be a difficult term to translate. Therefore, for the purposes of the survey, bullying was defined as follows:

"Sometimes children or teenagers say or do hurtful or nasty things to someone and this can often be quite a few times on different days over a period of time, for example. This can include: teasing someone in a way this person does not like; hitting, kicking or pushing someone around; leaving someone out of things."

During the interview, children were asked if this had happened to them either in person face-to-face, by mobile phone calls or texts, or on the Internet – e.g., via email, social networking sites.

Individual Level (Child as Unit)

Focussing in the first instance at the level of the individual child, data from the EU Kids Online survey allows us to describe the overall incidence of cyberbullying as reported by children aged 9 to 16 years. The survey found that 19% of children from across the 25 participating European countries, or one in five, reported that someone had acted in a hurtful or nasty way towards them. These children were then asked how it happened. The most common form of bullying reported was in person face-to-face at 13%, compared to 7% who reported that this happened to them on the Internet. The survey also found that for teenagers who experienced being bullied, this was more likely to be accompanied by online bullying and/or by bullying on mobile devices (Livingstone, Haddon, Görzig, & Ólafsson, 2011b).

Drawing on the full survey findings, individual level factors may be further elaborated as follows:

- Age and gender: There is little consensus in the literature on how various socio-demographic factors influence cyberbullying behaviour. Smith, Mahdavi, Carvalho, & Tippet (2006), for instance, find no effect of age among children aged from 11 to 16 years in the prevalence of cyberbullying, whereas Ybarra and Mitchell (2004) found that older pupils (15 years old and above) were more often Internet aggressors than a younger children's group (10-14 year-old). EU Kids Online, likewise, found some association of both age and gender with cyberbullying. Overall, as noted above, more bullying occurred offline than online: while 19% of children said they had been bullied either online and/or offline, just 6% of respondents reported being a victim of online bullying, while 3% said they had bullied others online. Within these findings, girls and older adolescents reported being cyberbullied more often than boys or younger children (Livingstone, et al., 2011b). Furthermore, bullying others online or via mobile phone was found to increase slightly with age. The data also showed that there was a link between offline and online bullying: 56% of online bullies said they had bullied others face-to-face and 55% of online victims of bullying also claimed to be victims of face-to-face bullying. Although being bullied online was generally more common among older children, no particular age trend in forms of bullying was evident (Görzig, 2011; Lampert & Donoso, 2012).
- Psychological factors: EU Kids Online included items adapted from the Strengths and Difficulties Questionnaire (SDQ) using items measuring psychological difficulties only, examining children's level of self-efficacy, sensation seeking, experiences of ostracism, and psychological difficulties. Generally, both cyberbullying victimisation as well as perpetration showed a positive relation with psychological difficulties, self-efficacy, and sensation-seeking (Lampert & Donoso, 2012; Laurinavičius & Zukauskienė, 2012). Moreover, it also appears that those involved in online bullying showed overall a higher level of psychological vulnerability than those not involved in online bullying (Hasebrink, Görzig, Haddon, Kalmus, & Livingstone, 2011).
- Cyberbullies compared to face-to-face bullies were more likely to engage in risky online activities, spend more time online, and find it easier to be themselves on the Internet – a pattern that remained stable across countries suggesting that it is individual level factors rather than the country level that are generally more important in explaining cyberbullying (Görzig & Ólafsson, 2013).

Family Level (Household as a Unit)

Socio-economic status was the principal variable used by EU Kids Online to detect possible differences at the level of the household. This was included primarily to examine questions of digital advantage or disadvantage, following on from previous research on the so-called “digital divide” (Livingstone & Helsper, 2007). Findings from the survey showed that the risk of being involved in either online or offline bullying increased slightly with higher levels of socio-economic status, although differences were small (Livingstone et al., 2011b). However, among youth who were involved in online bullying, those with a higher SES were more often involved as a bully, while those with a lower SES were more often involved as victims (Görzig, 2011). Young people from lower SES households also indicated more and a higher intensity of harm

than those from a higher SES background. Lower levels of SES were related to a less likely occurrence of some coping responses, specifically changing Internet settings, responding by deleting a message, or trying to fix the problem (Vandoninck, d'Haenens, & Smahel, 2014). Furthermore, young people from families classified as a minority group reported higher experiences of being bullied online as well as subsequent harm (d'Haenens & Ogan, 2013). Moreover, youth more often sought support upon being victimised if they belonged to a discriminated against group or spoke a minority language at home (Livingstone, Kirwil, Ponte, & Staksrud, 2014).

- **Socio-economic status (SES):** Some SES variation was found among those who responded to at least one of the questions regarding bullying and/or bullying others. However, the differences were minor. Among those who have experienced online bullying, girls, younger children, and those from a low socio-demographic background were more likely to be victims of bullying (and less likely to bully others) than boys, older children, and those with a higher socio-demographic background (Livingstone et al., 2011b). Overall, these differences suggest that those socio-demographic groups that are in some way or other more vulnerable are also more likely to report being victims than perpetrators of online bullying (Lampert & Donoso, 2012).
- **Parental factors:** Some differences were also found between parents' awareness of their child's experience of cyberbullying compared to more general awareness of their child's Internet activities. Overall, both 6% of children and 6% of parents reported that the child had been bullied on the Internet. Slightly more girls than boys (7% vs. 5%), and slightly more older teenagers (7% of 15-16 years) than younger children (3% of 9-10 year olds) said they had been bullied. There was a high level of agreement between children and their parents regarding whether or not the child had been sent hurtful or nasty messages on the Internet or bullied online. At the same time, there are some small, but noticeable, country differences in relation to the child/parent gap in perceptions. The child/parent agreement is a little lower in countries such as the Netherlands, Finland, Sweden, and Norway in that parents are more likely to think their child has been bullied online even when the child says they have not. By contrast, in Romania, Estonia, Bulgaria, the Czech Republic, and Hungary, children are more likely to say they have been bullied online than are parents.

Cross-Cultural/Cross-National Perspectives (Country as a Unit)

A powerful feature of the EU Kids Online survey was its combination of a pan-European survey interviewing some 25,000 children about their online experiences whilst also incorporating representative samples in each of the 25 participating European countries, thereby enabling detailed analysis at a national as well as the European level. Differences in Internet usage among European countries can have several explanations: for instance, how well established the infrastructure for the Internet is, the degree to which Internet safety awareness is disseminated, or more widely cultural factors that impact on parenting styles (Livingstone, Mascheroni, Dreier, Chaudron, & Lagae, 2015). All of these aspects constitute cultural differences that can be explored via quantitative or qualitative approaches. For instance,

opportunities, risks, harm, as well as parental mediation can be analysed and provide detailed information in terms of cultural as well as national contexts (Helsper, Kalmus, Hasebrink, Sagvari, & Haan, 2013).

Assessment of cultural differences remains a complex problem requiring a combination of approaches for identifying and discussing cross-cultural differences. The cultural level, for instance, may comprise abstract influences such as economic, social, educational, legal, or political systems which, in keeping with Bronfenbrenner's ecological model, can elicit indirect influence upon individuals and other levels of the ecological system (Bronfenbrenner, 1997). For explanatory purposes, EU Kids Online developed a classification of countries according to the amount and types of Internet use and risks (Lobe, Livingstone, Ólafsson, & Vobed, 2011). This approach was underpinned by the underlying trend consistent in all instances of the more Internet use, the more risk was found. As such, participating countries were classified into the following four groups:

- “*Lower use, lower risk*” countries (Austria, Belgium, France, Germany, Greece, Italy, Hungary) – here children made the lowest use of the Internet, and they were below average on all risks apart from meeting online contacts – online and offline; still, it may be expected that as levels of use rise in these countries, so too will risk.
- “*Lower use, some risk*” countries (Ireland, Portugal, Spain, Turkey) had the lowest Internet usage, although there was some excessive use of the Internet and some problems with user-generated content.
- “*Higher use, some risk*” countries (Cyprus, Finland, the Netherlands, Poland, Slovenia, the UK) made high use of the Internet but were high only on some risks, possibly because of effective awareness-raising campaigns, regulatory strategies, or strategies of parental mediation of children's Internet use.
- “*Higher use, higher risk*” countries (Bulgaria, Czech Republic, Denmark, Estonia, Lithuania, Norway, Romania, Sweden) include both wealthy Nordic countries and Eastern Europe that have the highest Internet usage across Europe as well as Eastern European countries with lower income but through more recent broadband investments experience “new use, new risk.”

Country differences for experiences of being bullied both face-to-face and online are noteworthy. Findings from EU Kids Online show that cyberbullying appears to be more common in countries where bullying in general is more prevalent rather than in countries where the Internet is more established. For example, in Romania and Estonia, more than four in 10 children report having been bullied, twice the average across all 25 countries included in the survey. Online bullying in these countries is also more than twice the average, at one in seven children who use the Internet. As such, levels of all forms of bullying, and experiences of victimisation and perpetration of cyberbullying go hand in hand. Variance at the country level represents a more complex issue. According to Görzig (2012), 7% of the variance in cyberbullying victimisation can be explained by aspects located at the country level. Gender differences (i.e., girls) were found to be the most important predictor of cyberbullying victimisation in Spain, the Netherlands and Finland. Higher Internet usage was found to be more significant in Greece, Hungary, Italy, and Slovenia. Then, risky online activities were the most relevant predictor in Bulgaria, Denmark, Poland, Portugal, and Sweden and the lowest in

Turkey, Hungary, and Lithuania. Reviewing the evidence for the variation in cyberbullying and its correlates across countries, Görzig and Machackova (2015) conclude that the cultural or country level does play a role in cyberbullying even if it is one of an array of factors within a socio-ecological system.

OFFLINE VS. ONLINE VICTIMS AND PERPETRATORS

Two key questions within the literature on bullying which were explored further by EU Kids Online are the relation between traditional offline bullying and online bullying, and the relationship between victims and perpetrators of online bullying, including the psychological profiles of those who have experienced both.

EU Kids Online findings show that across Europe, 6% of 9 to 16 year-olds who use the Internet report having been bullied online while only half as many (3%) admit to having bullied others. Since 19% have been bullied either online and/or offline, and 12% have bullied someone else either online and/or offline, clearly more bullying occurs offline than online (Görzig, 2011). There is a link between offline and online bullying however. Fifty-six percent of online bullies said they had bullied others face-to-face and 55% of online bullying victims also claimed to be victims of face-to-face bullying. As such, bullying and being bullied tend to go together. Among those who do not bully others, being bullied is relatively rare – 8% offline only, and 4% online. But, among those who have bullied others offline, nearly half (47%) had also been bullied offline (and fewer online). On the other hand, among those who had bullied others online, nearly half (40%) had been bullied online (and fewer offline) (Görzig & Machackova, 2015; Hasebrink et al., 2011).

Findings from EU Kids Online also show how the odds for a child to perpetrate bullying online compared to offline increase when one of the factors is changed by one unit. Specifically, it is shown that the odds of being an online bully as opposed to an offline bully increased by 48% when the child was a girl compared to a boy; by 28% when the child's belief in his or her Internet abilities increased by one point (of three); by 36% when the child's score on the "online persona" scale increases by one; by 30% when the child spent an additional hour online; by 31% when the child engaged in one additional risky online activity, and by 5% when the child engaged in one additional risky offline activity (Hasebrink et al., 2011).

Additionally, offline bullies were more likely to be boys rather than girls. However, when it comes to online, the likelihood of girls being bullies increased more than for boys. The consequence is that boys and girls are equally likely to bully online (but not offline). In sum, these findings suggest that online bullies can be differentiated from offline bullies on the basis of their behaviour and attitudes associated with the Internet as well as their gender rather than on the basis of their offline behaviours.

Online bullies and those being bullied online are those children who are mostly also vulnerable offline. This supports previous findings that those children who already face problems offline are not only in need of support in their offline lives but also in their online lives. This includes children who have psychological difficulties, are socially excluded (ostracised), engage in unhealthy sensation-seeking behaviours or are in some way or other members of a vulnerable group (Hasebrink et al., 2011).

Children who are bullied and/or bully others online have similar demographic and psychological profiles to those who are bullied and/or bully offline, suggesting that those children bullied or bullying online are not very different from those bullied or bullying offline except in that they make use of the affordances of the Internet (for example, the chance to meet new people online or to network with peers).

Those children who are causing harmful experiences online to others in the form of bullying are often the very same ones being bullied online by others, some of them known and some unknown to them offline. It is possible that being bullied by others online can sometimes be the response to having bullied others online, and vice versa, bullying others online can sometimes be the response to being bullied by others online. Although we cannot determine which is the cause and which the effect, providing more support for children who are victims of bullying might simultaneously decrease the occurrence of online bullying. Similarly, working to prevent children from engaging in online bullying behaviours might reduce the chance that they themselves will be bullied online by others. On a positive note and to keep these findings in perspective, it was shown that 93% of European children have neither been bullied nor bullied others online.

TRENDS OF BULLYING ONLINE AND OFFLINE

Following completion of the EU Kids Online survey in 2011, a new project called Net Children Go Mobile was undertaken in 2014, also supported by the European Commission's Safer Internet Programme. Closely modelled on the original EU Kids Online survey, Net Children Go Mobile provides time-series data for experiences of online risks and safety in a subset of countries allowing for the identification of trends (Livingstone, Mascheroni, Ólafsson, & Haddon, 2014). With new data from seven of the original 25 countries, Net Children Go Mobile shows that while overall incidence of bullying has not increased since the EU Kids Online survey, cyberbullying is now more prevalent than face-to-face bullying and occurs most commonly on SNS. This shift in experiences from bullying offline to online is most noticeable for girls and for early teenagers and is markedly a feature of increased use of mobile technologies such as smartphones and tablets (O'Neill & Dinh, 2015).

Overall levels of bullying have risen marginally from 21% to 23% (Mascheroni & Ólafsson, 2014). However, the number of children who report being bullied online or through any form on the Internet or mobile phones has nearly doubled from 7% to 12% in the period from 2011 to 2014. An increase in bullying among girls, and a slight decline among boys, is noteworthy. This is especially the case in relation to girls' reports of cyberbullying, where almost a doubling of online bullying from 8% to 15% is reported. Age variations are also significant in this sense. There are increased reports of bullying among young children, 9–10 years of age, and among 13–14 year olds. Older teens aged 15–16 years as well as 12–13 year olds reported a slight decline in experiences of being bullied. However, reports of cyberbullying have increased among all groups. The most substantial increase is in fact among younger users, aged 9–10 years old, where reports have tripled from 3% to 10% between 2011 and 2014, and doubled among 13–14 year olds, from 8% to 15% (O'Neill & Dinh, 2015).

The proportion of children who have been bullied at all (on and/or offline) has remained fairly stable at under a quarter of 9–16 year olds – except that it rose markedly in Denmark, and

was already very high in Romania. But, cyberbullying has increased in the past four years – from 8% to 12%, especially among girls, and among the youngest age group (aged 9-10 years, followed by teenagers aged 13-14 years old). The biggest increase from 2010 to 2014 in the percentage of children who have been cyberbullied is in Denmark (a rise from 12% to 21%) and Ireland (from 4% to 13%) (Mascheroni & Ólafsson, 2014).

CONCLUSION

Cyberbullying remains one of the most discussed forms of harmful behaviour resulting from young people's extensive participation online. High profile examples of threatening aggression and harassment of vulnerable young people, sometimes with tragic consequences, continue to dominate public discourse, especially in popular media, resulting in repeated calls for more direct intervention. Against this, EU Kids Online has, in common with other international reviews (Hinduja & Patchin, 2012), cautioned against the conclusion that cyberbullying has reached epidemic proportions. On the contrary, cyberbullying represents a subset and is best treated as a variant of unwanted, anti-social behaviour that can have damaging and sometimes devastating consequences for victims.

The value of large scale, multi-national studies such as that undertaken by EU Kids Online is that findings can provide a solid baseline for policy development and where necessary targeted intervention. As discussed, EU Kids Online has at its origins a commitment to evidence-based policy recommendations and over the course of the project has contributed to findings for policy making at both the country and European levels. Indeed, it is this combination of detailed socio-ecological data on the full range of young people's experiences, positive and negative, that has enabled the generation of significant discussion of policy responses that are measured, informed by evidence and addressed to the multiple stakeholders involved in supporting better Internet experiences for young people (Livingstone, Ólafsson, O'Neill, & Donoso, 2012; O'Neill & Staksrud, 2012).

Arising from findings of EU Kids Online is evidential support for the general proposition that individual level factors highlighting the needs of vulnerable populations, victim support and specific groupings more likely to engage in cyberbullying behaviour merit more targeted policy measures. The multiple cultural factors notwithstanding, there remains a universality to the experience of bullying behaviour which, as more recent data shows, is migrating on an increasing basis to online platforms. This is a timely reminder of the need to maintain a strong evidence base and to continue to monitor on a pan-European basis the diversity of issues that impact young people's online experience.

Chapter 143

CYBERBULLYING IN SOUTH KOREA

Seung-Ha Lee*

Department of Early Childhood Education,
Yeungnam University, South Korea

INTRODUCTION

Early studies of cyberbullying in South Korea focused on people's aggressive behaviour in cyberspace rather than those of school pupils (i.e., *aksung-daekgul* [malicious reply], *cybermoyok* [insults], *cybersungpokryuk* [sexual violence or sexting], cyberstalking etc.). Public concern for cyberbullying among school pupils was greatly raised by a middle school pupil's suicide in 2011. One middle school boy died by suicide after serious school bullying, including cyberbullying. The boy had been insulted, extorted, and received both waterboarding and physical attacks. The aggressive behaviours happened consistently through, or by, his mobile phone. He suffered serious mental torture, which destroyed his daily life and led to the suicide. In 2012 a high school girl died by suicide after receiving swearing and *flaming* from several peers in the chatroom. Finally, the South Korean government announced cyberbullying as a sub-type of school bullying in 2012, and have made efforts to prevent cyberbullying in line with traditional school bullying.

TERMS FOR BULLYING AND CYBERBULLYING

There are several terms to indicate bullying-like behaviours in South Korea and the terms are also related to those of cyberbullying: *gipdan-ttadolim* (group isolation), *gipdan-gorophim* (group harassment or group bullying), *hakkyo-pokryuk* (school violence), and *wang-ta* (*socially excluded person or social excluding behaviour*). These terms are often used interchangeably, but there are some differences in terms of the type of aggression each term most represents (Lee, Smith, & Monks, 2012). *Gipdan-ttadolim* and *gipdan-gorophim* imply group behaviours

* Corresponding Author's Email: seungha94@gmail.com.

(rather than one-to-one), and *hakkyo-pokryuk* includes a wide range of hostile and violent behaviours which happen among pupils, within or around schools, such as physical attack, name calling, *gipdan-ttadolim*, extortion of money, and sexual abuse. *Wang-ta* is a slang term popularized by pupils in the late 1990's, which means socially excluded person (victim) or excluding behaviour. Among these terms, the use of the term *hakkyo-pokryuk* has increased over time and a number of recent studies have used this term rather than other terms. Similar to traditional bullying, for cyberbullying there are several terms used in South Korea: *cybergorophim* (cyber-harassment), *cyberttadolim* (cyber isolation), *cyberpokryuk* (cyber violence), and *cyber wang-ta* (a socially excluded person in cyber space, or social exclusion in cyber space). Sometimes the English term *cyberbullying* is also used. Recently, the term *cyberpokryuk* has been most commonly used to indicate the corresponding phenomena to cyberbullying in western cultures because it includes a wide range of aggressive behaviours in cyber space.

DEFINITION

There is no agreement of definition of cyberbullying in South Korea. However, researchers generally agree that *cyberpokryuk* is an individual's harmful behaviour conducted by electronic communication equipment to specified or unspecified individual(s). The *Hakkyo-pokryuk Prevention and Counterplan Act* (2012. 4.1) indicated *cyberttadolim* (cyber isolation) as a subtype of *hakkyo-pokryuk*. It defines *cyberttadolim* as "the behaviours causing the other pupils' distress; a pupil/pupils aggress(es) other pupil(s) repeatedly, consistently or spread(s) personal- or false information using information technology equipment such as internet, mobile phone."

Table 1. Representative types of cyberbullying in South Korea

Types	Contents
Cybermoyok/bibang(insults)	Abusive words such as swearing, slander through the Internet, mobile text etc.
Cybermyungye-hweson (defamation)	Publicly posting messages/writings which harm an individual's honor.
Cyberstalking	Sending fearful or anxious emails/messages to someone or visiting his(her) SNS although (s)he does not want this.
Cybersungpokryuk (sexting)	Posting sexual description or sexual disparagement, sexual swearing of an individual using mobile or Internet, or spreading obscene video clip(s) or photograph(s).
Personal information drain	Spreading the other person's private information (name, address, school etc.).
Cybergangyo or cybermyungryung (coercion)	Forcing an individual to do an unwanted behaviour or errand. Compelling an individual to purchase cybermoney, cyber character, or other materials and make payment for him (her) (i.e., <i>wifi-shuttle</i> , <i>game item shuttle</i> etc.).
Cyberttadolim(exclusion), cybergorophim(harassment), cyber wang-ta	Isolating or excluding an individual in cyberspace through electronic communication means.

Kim and Yoon (2012a) defined *cyberpokryuk* as: “The verbally aggressive behaviours such as swearing, criticizing, threatening, rumor, *ttadolim* and *gorophim* which occur in cyberspace using electronic communication skills, and these behaviours cause psychological harm to (a) specified or unspecified person(s)” (p. 216). Lim (2013) used the English term cyberbullying and defined it as “...a new type of bullying: verbal-, non-verbal-, physical-, and relational bullying occurring in cyberspace using information communication skills” (p. 30).

TYPES OF CYBERBULLYING

Generally, studies in South Korea tend to categorize types of cyberbullying by its contents or behaviours rather than the place it occurs or the media used. Table 1 below summarizes some of the main types of cyberbullying which are commonly investigated in Korean studies.

The Korean Internet & Security Agency (KISA, 2011) divided the adverse effects of the Internet into two categories *cyberpokryuk* and *cyberbumjoi* (cybercrime). The former indicates behaviours which give a person unpleasant feelings, such as a malicious Internet reply, cyber-insults, personal information drain, cyber sexual abuse, and cyberstalking. When these behaviours are against the law, they are *cyberbumjoi*. However, it is not clear to what extent a certain behaviour is against the law. Some types of cyberbullying, cyber-insults, cyberstalking, and sexting have similar meanings to those of Western studies, whereas there is a distinctive phenomenon in South Korea, called *cybergangyo* (*wifi-shuttle*), which compels a victim to do/deliver whatever a bully/ cyberbully wants. The victim purchases what the bully asks and the costs of the materials are paid for by the victim. For example, charged data, game money, or game items can be the materials, and the victim conveys the resources to the bully after downloading on his/her mobile phone/tablet. Pupils usually call this “wifi shuttle,” because this is carried out by mobile or wireless service. If this is for a specific Internet game or related to game items, they call it “game shuttle.” This type of cyberbullying tends to be deeply related to traditional bullying in school. Although this is a serious type of *hakkyo-pokryuk*, studies including this are very much lacking.

PREVALENCE OF BULLYING AND CYBERBULLYING

Prevalence of *hakkyo-pokryuk* has been investigated by researchers, private, and national institutions, with samples randomly selected among schools across regions. However, the South Korean government has recently been investigating the prevalence of *hakkyo-pokryuk* twice a year for all school pupils aged 11-18 years (N = 4,980,000). Pupils are asked about their bully/victim experience for the last semester, or the last 6 months. The results have shown that receiving *hakkyo-pokryuk* (school violence) has been rapidly decreasing in the recent 2-3 years (see Table 2 below). Figure 1 shows the percentages receiving each type of *hakkyo-pokryuk*. As a subtype of *hakkyo-pokryuk*, *cybergorophim* has been increasing from 2012 (7.2%) to 2013 (9.7%), and has been remaining constant at around 9% (Ministry of Education, 2014).

Table 2. Percentage of incidence of being victims of *hakkyo-pokryuk* from 2012 to 2014 (Ministry of Education, 2014)

Levels of school	2012 1 st	2012 2 nd	2013 1 st	2013 2 nd	2014 1 st
Elementary school	15.2	11.1	3.8	2.7	2.4
Middle school	13.4	10.0	2.4	2.0	1.3
High school	5.7	4.2	0.9	0.9	0.6

Note. Adapted from “2014 Icha hakkyo-pokryuk siltae josa bunsuk gyeolgwabalpyo” [2014 Report of 1st *hakkyo-pokryuk* survey] by Ministry of Education, 2014.7.11 [Press release]. p. 4.

Figure 1. Percentage of receiving each type of *hakkyo-pokryuk* by school levels.

INCIDENCE OF CYBERBULLYING

Perpetrating Cyberbullying

Perpetrating cyberbullying varies across South Korean research studies, having shown rates of 7% to 40%. These results may reflect the different methods and approaches regarding the investigations (i.e., types of cyberbullying included, time reference period). KISA (2013) surveyed the prevalence of cyber*pokryuk* among 1,500 elementary, middle, and high-school pupils across 16 national regions. They provided a definition of each type of cyber*pokryuk* (cyber verbal violence, cyber defamation, cyber stalking, cyber sexual abuse, personal information drain, and cyberbullying [*ttodolim*]). They enquired about pupils’ experiences of cyber*pokryuk* in the preceding year. The results showed that 29.2% of the respondents reported experiences of doing cyber*pokryuk*; it was lowest in elementary school pupils (7%), with 39% of middle school pupils, and 38.4% of high school pupils reporting having done it.

Note. Adapted from “Cyberbullying siltaewa haebeop seminar balpyo jaryo [Prevalence and prevention of cyberbullying seminar. 2013. 12. 18.]” by NIA, 2013. Seoul. p. 20.

Figure 2. Percentage of perpetrating cyberbullying by its type (NIA, 2013)¹

The National Information Society Agency (NIA, 2013) investigated cyberbullying among 11,956 elementary (5th and 6th graders, aged 11-12 years), middle- and high-school pupils (aged 13-18 years). Figure 2 shows the incidence of cyberbullying by its type. As can be seen, *cyberbaejae*(exclusion) was most common, and *cyberbibang*(insults) showed similar findings.

Types of media used for cyberbullying was commonly found to be Messenger (kakaotalk, mypeople, line, etc.), cyber community (anti-café, social club), and SNS (Facebook, Twitter, blogs, etc.) (KISA, 2013). Lee, Hwang, and Yeum (2013) reported that cyberbullying was performed most commonly through mobile phone (58.5%), followed by Messenger (21.5%).

Gender Differences of Perpetrating Cyberbullying

In a general way, boys were more likely than girls to perpetrate *cyberpokryuk* (KISA, 2011; Lee et al., 2013; Shin, & Ahn, 2013), but differences were not statistically significant in some

¹Cyberstalking: Sending fearful or anxious emails/messages to someone or visiting his(her) SNS although (s)he does not want this; *Cyberbibang*: Abusive words such as swearing, slander through the Internet, mobile text etc.; Imagebullying: Posting or spreading someone's photos or video clips so as to insult that person. ; ID theft: Using other's ID and pretend to be the owner of the ID; *Cybergalchui*(extortion): Forcing someone to purchase or buy something which a perpetrator wants to have, by using the victim's smartphone or Internet payment system; *Cybersungpokryuk*(sexting): Posting sexual description or sexual disparagement, sexual swearing of an individual using mobile or Internet, or spreading obscene video clip(s) or photograph(s); *Cybergameum*: cyber jail, which confines someone in an Internet chat room and swearing or insulting him/her. *Cyberttadolim*(exclusion): Excluding someone in cyberspace; Flaming: Invoking someone by intentionally starting argument to him/her; *Cybermyungryung*(coercion): Forcing someone to do what he/she does not want to do using Internet or smartphone; Anti-café: Internet communities or websites which have been set up for excluding and slandering someone; *Cyber wang-ta* play: several people make someone *wang-ta*(socially excluded person) by insulting, swearing, or denigrating him/her in cyberspace.

studies (Shin, & Ahn, 2013), or the differences of the means of perpetrating *cyberpokryuk* between boys and girls were not statistically tested in other studies (KISA, 2013; NIA, 2013).

There were more boys than girls involved in cyber verbal violence, cyber defamation, cyber stalking, cyber sexual abuse, and personal information drain. Girls were more likely than boys to perpetrate *cyberttadolim* (KISA, 2013), but statistical significance was not tested.

NIA (2013) reported that boys were generally more likely than girls to cyberbully. However, in cyberexclusion (called, *cyberbaejae*), there was a higher percentage among girls than boys (Figure 3 shows the ratio of perpetrating cyberbullying between boys and girls).

Who Participates in Cyberbullying?

More than half of the pupils surveyed knew who the cyberbullies were; 54.3% of elementary school pupils, 52.3% of middle school pupils, and 64.6% of high school pupils did *cyberpokryuk* to a pupil(s) whom they knew in their schools (KISA, 2013). Over half (55.4%) of cyberbullies replied that they chose the target from among the pupils in their school (Lee et al., 2013). Forty-three percent of cyber-victims replied that they were cyberbullied by their peer(s) in their school (Lee et al., 2013).

Reason for Perpetrating Cyberbullying

The most common reason for doing *cyberpokryuk* was “for fun” and to “upset the victim” in all school levels (KISA, 2013; NIA, 2013). The reasons for perpetrating cyberbullying differed by school level; among elementary school pupils, “for fun” was the most common reason stated (elementary: 45.7%; middle: 29.7%; high: 33.3%), however, among middle-, and high-school pupils “upset for the victim” was the most frequent reason for cyberbullying (elementary: 34.3%; middle: 68.2%, high: 64.1%) (KISA, 2013). Furthermore, “no reason” (elementary: 22.9%, middle: 11.8%, high: 11.5%), and “getting along with friends” (elementary: 20.0%, middle: 5.6%, high: 12.5%) were also common responses (KISA, 2013).

How Do Pupils Feel after Cyberbullying/Being Cyberbullied?

A high percentage of elementary school pupils reported that “I don’t feel it as fault because I have done it for fun” (25.7%), “Sorry for the person” and “regret” were also common feelings after *cyberpokryuk* among pupils – ranging from 22.9% to 29.7% (KISA, 2013). However, “don’t feel anything” was also a common feeling about *cyberpokryuk* among pupils, which was higher in middle- (28.7%) or high-school pupils (24.0%) than elementary school pupils (20.0%).

Note. Adapted from “Cyberbullying siltaewa haebeop seminar balpyo jaryo [Prevalence and prevention of cyberbullying seminar. 2013. 12. 18.]” by NIA, 2013. Seoul. p. 20.

Figure 3. Gender ratio of perpetrating cyberbullying by its type (NIA, 2013).

Note. Adapted from “Cyberbullying siltaewa haebeop seminar balpyo jaryo [Prevalence and prevention of cyberbullying seminar. 2013. 12. 18.]” by NIA, 2013. Seoul. p. 20.

Figure 4. Percentage of being victims of cyberbullying by its type (NIA, 2013).

Being a Victim of Cyberbullying

KISA (2013) reported that 30.3% of pupils received *cyberpokryuk*; about 40% of middle-, and high-school pupils had been a cyber-victim during the last year, whereas only 7.4% of elementary school pupils had experienced being a cyber-victim. Adolescents (12-19 year olds) had most commonly received *cyberpokryuk* (75.8%), and the experience of this reduced according to age (from their 20's to their 50's) (KISA, 2011). KISA (2011) reported that 34% of elementary school pupils had experience of receiving *cyberpokryuk*; upper grade pupils (49.3%) had received *cyberpokryuk* which is three times more than pupils in lower grades (13.0%). Figure 3 indicates the percentages of being a cyber-victim by types of cyberbullying (NIA, 2013). The most common type of cyberbullying was *cyberbibang*(insults) followed by *cyberbaejae*(exclusion).

Gender Differences among Those Cyberbullied

Generally, boys were more likely than girls to receive *cyberpokryuk* (Lee et al., 2013; Shin, & Ahn, 2013). Cyber verbal violence, cyber defamation, personal information drain were more common amongst boys than girls. However, cyber sexual abuse was more common in girls than boys (KISA, 2013; Shin, & Ahn, 2013).

Figure 5 shows the gender ratio of being victims of cyberbullying (NIA, 2013). Depending on the type of cyberbullying, boys showed a higher ratio than girls. Cyber-exclusion showed a higher ratio among girls than boys. This may indicate that the girls tended to experience relational cyber aggression more often than boys.

Note. Adapted from "Cyberbullying siltaewa haebeop seminar balpyo jaryo [Prevalence and prevention of cyberbullying seminar. 2013. 12. 18.]" by NIA, 2013. Seoul. p. 22.

Figure 5. Gender ratio of being victims of cyberbullying by its type (NIA, 2013).

By school level, findings were not consistent. There were more girls than boys who received *cyberpokryuk*, whereas in the middle- and high-school levels, more boys than girls were victims of *cyberpokryuk* (KISA, 2013). However, a different study showed the opposite result: elementary school boys (36.2%) had more experiences of receiving *cyberpokryuk* than girls (31.9%) (KISA, 2011).

Responses after Being Cyberbullied

Common responses after being cyberbullied were “get [them] back in the same way” (39.4%), and “demand deletion or correction of the message to the cyberbully(ies)” (17.6%), and “claiming apologies” (17.1%). There was a high frequency who replied “no response” (36.5%) (KISA, 2011). By school levels, middle school pupils (50.3%) and high school pupils (40.9%) were more likely than elementary school pupils (29.7%) to demand that the cyberbully(ies) delete or correct the harmful writing or message. “Telling friends” (elementary: 35.1%; middle: 27.4%; high: 22.2%) and “telling parents/families” (elementary: 24.3%; middle: 16.8%; high: 6.4%) were also common. However, “telling [the] school teacher” (elementary: 8.1%. middle: 9.1% high: 4.9%) showed relatively low percentages. “Reporting [to the] police, Wee-centre (bullying and cyberbullying intervention centre), 117, cyber bureau of national police” showed least common responses (elementary: 5.4%. middle: 7.1% high: 4.4%) (KISA, 2013).

Whether the Coping Strategies Were Effective?

“Telling friends” was most helpful for stopping cyberbullying (elementary: 69.2%. middle: 75.9% high: 60.0%) and “telling parents/families” was also reported as helpful. Around half of pupils who asked cyberbully(ies) to delete or correct the messages reported success (elementary:45.5%. middle: 55.6% high: 48.2%). “Telling teachers” was completely useful (100%) at elementary school level, but much less useful in middle- (38.9%) and high-school (30.0%). Half of elementary school pupils who reported the incidents to the police, Weecentre, 117, or cyber bureau of national police thought it was helpful, and 42.9% of middle school pupils and 44.4% of high school pupils reported this as being effective (KISA, 2013).

Feeling after Being Cyberbullied

Many pupils who received *cyberpokryuk* felt psychological distress or difficulties in their social lives. Common responses were “having difficulty in getting along with friends” (elementary 18.9%; middle: 10.2%: high: 8.4%), “did not want to go to school” (elementary 21.6%; middle: 16.8%; high: 14.8%), did “want revenge” (elementary 21.6%; middle: 35.0%; high: 30.5%) (KISA, 2013). However, older pupils (middle: 34.0%; high school: 43.8%) tended to report “did not feel anything” compared to younger pupils (elementary: 29.7%) (KISA, 2013).

Witnessing Cyberbullying

Around 37% of middle-, and high-school pupils, and 12.6% of elementary school pupils had experience of witnessing *cyberpokryuk* (KISA, 2013). Almost half of them (48.6%) reported they did nothing after witnessing it because they thought of it as “nothing” (45.6%). “Don’t know what to do” was a common reason among elementary school pupils, whereas “it is nothing” was the most common reason among middle- and high-school pupils (KISA, 2013).

Reasons for Not Responding to Cyberbullying

Approximately 42% of pupils who received *cyberpokryuk* reported that they did nothing because “it may be not helpful” (64.4% of these respondents), particularly, elementary school pupils were afraid of being isolated more seriously after reporting the incident (28.6% of these respondents) (KISA, 2013).

RELATED VARIABLES

Individual Factors

Studies reported that some personal traits (i.e., aggression, impulsiveness, self-control) were related to cyberbullying behaviour (Kim & Yoon, 2012a; Nam & Kwon, 2013; Park, 2012). Kim and Yoon (2012a) investigated cyberbullying experiences of 1,303 middle-, and high-school pupils in South Korea in relation to their individual, home environment, and school factors. They found that aggressive traits of male pupils positively predicted cyberbullying behaviour (but not among girls). Similarly, aggression of both male and female pupils showed positive correlations with cyberbullying behaviour (Nam & Kwon, 2013, NIA, 2013; Sung, Kim, Lee, & Lim, 2006). Impulsiveness also influenced cyberbullying behaviour (Nam & Kwon, 2013). Self-control was negatively related to cyberbullying behaviours (NIA, 2013; Park, 2012). Nam and Kwon (2013) reported that guilty feelings were negatively related to cyberbullying behaviour. Oh (2011) reported that upper elementary pupils (aged 11-12 years) who had experiences of perpetrating *cybergorophim* showed lower levels of self-esteem than pupils who had not.

Cyber-victim experiences predicted internalizing (depressive symptoms) and externalizing problems (aggressive traits) which resulted in academic stress (Kim, 2013; Oh, 2013). Low levels of self-control were related to cyber-victim experiences (NIA, 2013; Park, 2012). The more cyber-victim experiences that the pupils had, the more suicidal thinking they tended to do (Seo, & Cho, 2013). Pupils who experienced cyber-victimization experiences in *cybergorophim* had lower psychological well-being than pupils who had not (Oh, 2011).

Home Environmental Factors

Adolescents’ involvement in cyberbullying was related to relationships with their parents’ behaviour (a violent home atmosphere). Kim and Yoon (2012b) reported that witnessing

parental violence and abusive experiences are positively related to cyberbullying behaviour. Furthermore, adolescents' attachment to their parents predicted cyberbullying behaviour; the less attached to their parents, the more cyberbullying behaviour adolescents showed (Sung et al., 2006).

Cyber-victim experiences were related to parental attention and degree of parental control to their children's Internet usage; these were negatively related to children's low level of cyber-victim experiences (Cho, 2013). Parent-child communication skills negatively predicted adolescents' cyber delinquency, and authoritarian and controlling parental attitude were related to it (Kim, 2014).

School Environmental Factors

Delinquent peers, low level of school satisfactions and bully or victim experiences in traditional bullying (i.e., face-to-face school bullying) are related to adolescents' involvement in cyberbullying. Having, or connecting with delinquent peers was a significant factor for cyberbullying behaviours (Kim, 2013; Lee, & Jeong, 2014; Nam, & Jang, 2011). Lee and Jeong (2014) examined several factors which may predict willingness to perpetrate cyberbullying behaviour among 514 middle-, and high-school pupils in South Korea. They investigated *hakkyo-pokryuk* victim experience, cyber-victim experience, contact with delinquent peers, child abuse experience, and subjective norm of cyberbullying (e.g., how other people perceive my cyberbullying), perceived behavioural control for cyber-bullying (e.g., I can do cyberbullying if I want to). They found that delinquent peers, and positive subjective norms of cyberbullying influenced their willingness to participate in cyberbullying behaviour. Also, the NIA (2013) reported that low levels of school satisfaction predicted cyberbullying behaviour experiences.

Bully or victim experiences in traditional bullying are related to cyberbullying. Many studies (e.g., Cho, 2013; Ryu, 2013; Sung et al., 2006) have indicated strong relationships between bullying in cyberspace and victimization in traditional bullying. Ryu (2013) surveyed 1,088 middle-, and high-school pupils' cyberbullying experiences in relation to their traditional school bullying experience in South Korea. The author found that cyberbullying experiences were positively correlated both with victim and bully experience of traditional bullying.

Cyber-victim experiences were predicted by bully or victim experiences in traditional bullying among adolescents (Cho, 2013). There were significant relationships between *gipdan-ttadolim* (group isolation) and cyberbullying. Victims as well as bullies of *gipdan-ttadolim* were more likely than non-victims of it to be either a cyberbully or a cyber-victim (Lee et al., 2013).

Among individual, home environment, school factors, cyber-victim experiences (from both unspecified and specified cyberbully) cyber-victim experiences was most influential predictor for cyberbullying (Jun, & Lee, 2010; Kim, & Yoon, 2012a; Sung et al., 2006).

PERCEPTION

There are not many studies on pupils' perception of cyberbullying. A few studies have investigated pupils' perception of cyberbullying (Kim, & Yoon, 2012a, b; Sung et al., 2006).

Kim and Yoon (2012b) reported that attitudes towards violence were related to individual's cyberbullying experience. They found that tolerance of violence mediated the relationship between victim/cyber-victim experiences, and cyberbullyingbehaviour; victim and cyber-victim experiences increased tolerance of violence, which positively influenced cyberbullyingbehaviour. Pupils' ethical sense was related to cyberbullying. Sung et al. (2006) indicated that a sense of ethics of information communication and experiences of punishment negatively predicted cyberbullying experiences. Many pupils were aware of the legal punishment regarding cyberbullying. Lee et al. (2013) reported that most of them (92.8%) replied that they were aware of legal punishments for perpetrating cyberbullying. Similarly, most middle-, and high-school pupils (92%), and more than half of elementary school pupils (67.8%) knew about legal punishments for cyberpokryuk. Girls were more likely than boys to be aware of this (KISA, 2013).

PREVENTION AND INTERVENTION

Laws and policies mainly focused on *hakkyo-pokryuk* and those of cyberbullying have been established recently. The *Hakkyo-pokryuk Prevention and Intervention Act* in 2012 regulated types of *hakkyo-pokryuk*, and *cyberttadolim* was indicated as one type of it. The Act indicates that the school must organize the committee of *hakkyo-pokryuk* if an incidence of *hakkyo-pokryuk* is reported. The committee consists of teachers, parents, judge, lawyer, or medical doctors. The committee deliberates upon the episodes, and decides upon actions: protection for victim, punishment to bully, conciliation between victim and bully, and intervention program for the bully and bully's parents, etc.

Studies or programs for prevention or intervention for cyberbullying have started since 2011/2012. Some websites which support governmental institutions were established to prompt action against the incidence of cyberbullying and to provide useful information for preventing cyberbullying. To intensify the reporting system, and expedite action for cyberbullying incidents, the Ministry of Education has operated an anti-bullying website called *stopbullying* since 2012 (<http://www.stopbullying.or.kr>). Anyone who is bullied can report their experience by telephone (117) or ask for help through the website or via mobile text – the pupil can then get help, including counselling services and coping strategies. This was operated anonymously, so that pupils can ask and obtain help when they are afraid of revenge or reluctant to reveal their name or position. Also, this site is connected to their school teacher, and if they want, their case can be talked with their school teachers.

The ethical culture regarding the use of the Internet or SNS has been emphasized. To increase the sensitivity of information ethics and to create a healthy Internet culture, the Korea Internet & Security Agency (KISA) operates a website (<https://www.iculture.or.kr>). This offers knowledge regarding the correct usage of the Internet, SNS, and diverse educational instructions by school levels.

Studies about prevention or intervention programs are few. The National Information society Agency (NIA) operates programs for information on ethics education. Schools can apply for the information ethics education program; teachers in the schools are trained and organize a pupils' community called *areumnuri-jikimi* which consists of 30-40 pupil-volunteers. The pupils are educated by the teachers and work to form positive usage in

cyberspace (i.e., increasing knowledge of cyberbullying, participating in prevention activities and conduct a campaign for correct Internet use).

These institutions and websites provide very useful information or programs but effectiveness of those programs has not been evaluated yet.

CONCLUSION

This chapter has looked at the studies from South Korean cyberbullying research, including findings about prevalence, related factors, and prevention/intervention efforts. Studies about cyberbullying among pupils have been actively conducted since 2011 and offer comprehensive information for the current state of cyberbullying in South Korea. Recent studies about cyberbullying in South Korea tend to use the term *cyberpokryuk* more so than other terms, because cyberbullying behaviour has become more diverse and the term includes wide ranges of cyber aggression. Verbal insult was the most common type of *cyberpokryuk* and *cyberttadolim*(exclusion) was common - particularly among girls.

There are many steps that are needed to move forward with cyberbullying studies in South Korea. Measurement issues (i.e., definition, types of, terms for, and a time reference period of cyberbullying) need to be better clarified, and there is a lack of studies about pupils' perception of, or attitudes towards, cyberbullying. Considering pupils' responses regarding reasons for bullying (i.e., "no reason," "for fun," "upset for the victim"), and justification of cyberbullying, an important concern to decrease cyberbullying in South Korea is to increase the knowledge of cyberbullying, and to change pupils' perceptions through education. It is strongly required to educate pupils in relation to empathy, respect for others and moral responsibility for their behaviour. Current websites for preventing cyberbullying provide good examples of this.

Individual, home, and school related factors regarding cyberbullying have been investigated among Korean studies. These factors should be considered when developing prevention or treatment programs and helping victims and bullies. Studies suggested a need for concern and efforts by government, community, school, and home for announcing that cyberbullying is seriously harmful behaviour and emphasizing an ethical Internet culture. Current efforts provide good examples of this, but this is just beginning. Future studies and attempts should be provided for preventing Korean bullying.

Chapter 144

NEEDS, DETERMINANTS, COPING AND STAND-ALONE INTERVENTIONS

Francine Dehue*, Tijtje Völlink and Nicole Gunther

Faculty of Psychology and Educational Science,
Open University of the Netherlands, Heerlen, Netherlands

INTRODUCTION

Cyberbullying is a phenomenon that has been linked with several serious negative outcomes for both the victims and organizations (e.g., schools), including anxiety (Bauman, Toomey, & Walker, 2013; Campbell, Spears, Slee, Butler, & Kift, 2012), depression (Goebert, Else, Matsu, Chung-Do, & Chang, 2011; Helweg-Larsen, Schütt, & Larsen, 2012; Lam & Li, 2013), lower levels of self-esteem (Patchin & Hinduja, 2011), suicidal ideation (Goebert et al., 2011; Hinduja & Patchin, 2010), substance abuse (Mitchell, Ybarra, & Finkelhor, 2007), psychosomatic problems (Sourander, 2010), absenteeism, truancy, and decreased performance in school (Beran & Li, 2007; Schneider, O'Donnell, Stueve, & Coulter, 2012).

NEEDS ASSESSMENT

Analysing the problem amongst children and young people (CYP) involved in cyberbullying is an important first step in reaching the population at risk (prevention of cyberbullying) and in need of help (combatting cyberbullying and buffer the negative consequences). However, in the field of cyberbullying research there is still a lot of discussion about fundamental questions like the number of victims, bullies, and bystanders which are in need of help (see Kerstens & Wilsem, 2012), whether cyberbullying is just another form of traditional bullying and thus should be prevented and combatted together (Wolke, Lera, & Tipett, 2015), whether it is an overrated phenomenon (Olweus, 2012), and whether cyberbullying is an antecedent for mental well-being or a consequence of low negative well-

* Corresponding Author's Email: francine.dehue@ou.nl.

being (Gunther, DeSmet, Jacobs, & De Bourdeaudhuij, 2015). This paragraph describes some important features of the population at risk (prevention) and in need of help (combatting cyberbullying and buffering negative consequences).

Factors Influencing the Variation in Cyberbullying Prevalence

In a brief history of cyberbullying research Peter Smith (2015) informs us that there is a huge variation in the prevalence of cyberbullying and that this is caused by: (a) the strictness of the timeframe, varying from at least one cyberbullying experience in their life time (Tokunaga, 2010) to once a month during the past six months, or at least twice or three times a month during the past six months (Solberg & Olweus, 2003; Vandebosch et al., 2006), (b) the direct versus indirect assessment method (e.g., “Are you the victim/perpetrator of cyberbullying?” versus “Which of the following behaviors did you experience and how often?”) (Vandebosch & Van Cleemput, 2009); (c) the description of the cyberbullying phenomenon preceding the direct assessment; (d) the cut-off score used to define a victim, bully, or bully/victim; (e) the nature and age of the sample; and (f) the year of data collection. These factors should be taken into account when the population at risk (for prevention purposes) and the population in need for help (for combatting and buffering the negative effects) is defined.

How to Choose an Instrument to Measure Cyberbullying Involvement

The direct versus indirect assessments used to rate the prevalence of cyberbullying has an enormous impact of the prevalence rates and the selected population. A study by Vandebosch and Van Cleemput (2009) in which the direct as well as the indirect method was used for cyberbullying assessment can demonstrate the differences in prevalence rates: when asked directly whether they had ever been actively or passively involved in bullying via the Internet or mobile phone, 11% answered that they had been a victim, 18% had been a perpetrator, and 28% had been involved as a bystander. When measured indirectly, the percentage of respondents who had experienced at least one form of 12 potentially offensive Internet and mobile phone practices was much higher: 62% had been victim, 53% had been perpetrator, and 76% had been bystanders.

The question remains which of the assessments will be the most adequate to select children involved in cyberbullying for standalone ICT interventions. Vandebosch and Van Cleemput (2009) concluded that measuring respondents' experiences with a range of negative online experiences presumed to represent forms of cyberbullying, without taking into account the context in which these activities take place and the interpretations of those involved, is not an adequate method to investigate cyberbullying since it leads to over-estimations of the problem. We agree with the researchers, however for selecting CYP for a standalone ICT intervention aimed at preventing negative experiences, the broad objective indirect assessment is more suitable. For interventions aimed at combatting cyberbullying and buffering the negative impact, the subjective direct assessment is more suitable, since this will lead to a selection of CYP that perceive themselves to be involved in cyberbullying. Additionally, for this target population it is also important to explicitly measure the need for help: Kerstens and Wilsem

(2012) found that 24% reported being involved in at least one of five specific types of cyberbullying (e.g., spreading gossip, name-calling and threats, exclusion, sending or uploading upsetting photos and/or videos) in the past three months, but only 9% of them reported feeling bothered or upset by (one) of these negative experiences.

Time Frame to Assess Cyberbullying

Concerning the time frame, we believe that it is more adequate for stand-alone ICT interventions to take a rather short time frame. For the preventive ICT intervention the past three months might be a proper time frame: their negative experiences might evoke interest among these CYP for preventive tips, whereas for interventions aimed at combatting cyberbullying and buffering the negative affects a more stringent time frame (the past few weeks/days) might be more suitable, since these interventions are focused on CYP that directly need help. However, this must be explored in more detail.

IMPORTANT AND CHANGEABLE DETERMINANTS THAT INCREASE VULNERABILITY FOR NEGATIVE OUTCOMES

The purpose of this part of the chapter is to analyse some individual and contextual changeable determinants that increase adolescents' risk of being cyber victimized, and consequently increase adolescents' vulnerability for negative outcomes. The study of the determinants of cyber victimization is relatively recent, and although some consistent findings have been found, so far there are still some gaps and inconsistencies (Álvarez-García, Pérez, González, & Pérez, 2015; Menesini & Spiel, 2012). Given the fact that most of the studies are correlational (= cross-sectional), causal claims cannot always be made. Nevertheless, even without being able to establish causality, knowledge on these relationships may provide valuable insights for understanding and reducing cyber victimization.

Among the determinants on the individual level, self-esteem has been relatively consistently associated with being the victim of cyberbullying. Victims of cyberbullying often have lower levels of self-esteem (Patchin & Hinduja, 2011) and a low self-esteem has been mentioned as a predictor of cyber victimization rather than an outcome, as several longitudinal studies have found that lower self-esteem at baseline was associated with cyber victimization at follow-up (Modecki, Barber, & Vernon, 2013; Yang et al., 2013). Also, in a longitudinal study by Hemphill and Heerde (2014), it was concluded that emotion control in adolescence (e.g., the ability to control one's own temper when somebody is angry) protected against being a victim of cyberbullying in young adulthood. In addition, in a cross-sectional study, it was shown that, beyond cultural differences, low self-control (= a manifestation of self-regulation capacity) was directly as well as indirectly (via e.g., externalizing behaviour) linked to cyber victimization (Vazsonyi, Machackova, Sevcikova, Smahel, & Cerma, 2012). Furthermore, overall lack of self-efficacy (i.e., an individual's belief in his or her ability to execute behaviors necessary to produce desired outcomes (Bandura, 1977) as well as having poor social skills (Navarro, Yubero, Larrañaga, & Martínez, 2012) were positively associated with victimization, and victims have been consistently found to show low levels of perceived social intelligence

(Hunt, Peters, & Rapee, 2012; Schultze-Krumbholz & Scheithauer, 2009). Cyber victimization has been correlated with high levels of moral disengagement (Kowalski, Giumetti, Schroeder, & Lattanner, 2014). Also internalizing problems predicts cyber victimization over time (Reijntjes, Kamphuis, Prinzie, & Telch, 2010).

Previous research clearly shows that traditional bullying is one of the strongest predictors for cyberbullying (see Wolke, Leraya & Tipett, 2015) and young people who experience both traditional and cyber victimization are at particular risk of experiencing negative emotions (see Gimenez-Gualdo, Hunter, Durkin, Arnaiz, & Maquilon, 2015).

Lastly, technological determinants have been linked with cyber victimization. Most of the previous studies demonstrated that frequency of Internet use related positively with cyber victimization (see for a review: Álvarez-García et al., 2015; Kowalski et al., 2014). For example, victims of cyberbullying were found to engage in high levels of Internet use (Wolak, Mitchell, & Finkelhor, 2007), spend more hours per day using a computer than those who were not victimized (Mishna, Khoury-Kassabri, Gadalla, & Daciuk, 2012). Also weekly online game use predicted cyber victimization (Chang et al., 2015). In addition, Internet risk behaviors are consistently associated with cyber victimization. In recent cross-sectional and longitudinal studies, risky Internet behaviors have been shown to be strongly associated with and strongly predict cyber victimization (Álvarez-García et al., 2015; Chang et al., 2015; Helweg-Larsen et al., 2012). In a meta-analysis (Kowalski et al., 2014) investigating risk and protective factors of cyber victimization, it was concluded that one of the largest effect sizes (although still small), was observed for risky online behavior. As such, children who were more often cyberbullied have been found to be less aware of the risks involved in particular uses of the Internet, such as sharing passwords with others, publishing personal information on a blog, or talking with individuals they did not know in their offline lives (Hinduja & Patchin, 2009; Mishna et al., 2012; Walrave & Heirman, 2011).

Regarding contextual determinants, one of the most frequently analysed determinants that specifically relates to cyberbullying has been parental control of technology, that is, the extent to which parents monitor children's use of technology and have an element of control over their child's online behaviour. Kowalski et al.'s (2014) summary of findings shows that cyber victimization is associated with reported low levels of parental control of technology (see also Aoyama, Utsumi, & Hasegawa, 2012). It seems that families of victimized adolescents usually established less rules about Internet usage and used filter software less often than families of non-victimized adolescents (Mesch, 2009), that cyberbully victims are more likely to have an e-mail account not accessible to parents (Twyman, Saylor, Taylor, & Comeaux, 2010) and that parental control was a risk factor of cyber victimization (Álvarez-García et al., 2015). In contrast, other studies showed that there was no statistically significant association between parental control and cyber victimization (Mishna et al., 2012; Zhou et al., 2013). Positive and negative parenting styles have also been studied in relation with cyber victimization. In a recent meta-analysis, it was found that cyber victimization was related to less parental involvement and support, less warmth and affection, worse parent-child communication, less positive and more negative parenting in general, more abuse and neglect, maladaptive parenting, and overprotection (Lereya, Samara, & Wolke, 2013; Dehue, Bolman, Völlink, & Pouwels, 2012). In addition, it was shown that adolescents living in single-parent homes who were exposed to low family and low peer support were at a greater risk for being cyber victimized in the future (Fanti, Demetriou, & Hawa, 2012). Therefore, in line with Hodges and Perry (1999) it was suggested that interpersonal risk is an important factor in predicting cyber victimization, and

this is especially true for children from single-parent families (Fanti et al., 2012). Other studies did not find parental support to be predictive of cyber victimization (Black, 2014). Kowalski et al. (2014) also identified a number of school risk factors of cyber victimization: individuals who report higher levels of cyber victimization also report lower levels of school safety and school climate.

In conclusion, some young people are more at risk of being cyber victimized than others. However, not all young people who encounter cyberbullying suffer negative effects. Most children do not report being bothered and respond in a positive way to risky online experiences (Livingstone, Haddon, Görzig, & Ólafsson, 2011). In other words: they are resilient in the face of cyberbullying (i.e., have the ability to deal with negative experiences online). In contrast, some children feel more upset and experience more difficulties in responding effectively to cyber victimization. These reactions to the demands of a stressor (e.g., receiving a hurtful e-mail) is called coping and can be defined as the cognitive and behavioral effort employed to reduce, master, or tolerate internal and external demands that are the consequence of stressful events (Lazarus & Folkman, 1984). Besides understanding who is most at risk of cyber victimization, a better understanding of the process of coping with cyber victimization is important in order to develop behavioral change programs (Bartholomew, Parcel, Kok, & Gottlieb, 2006) to help young people adequately cope with cyberbullying and consequently reduce victimization of cyberbullying and its negative effects, which is to develop online resilience.

EVIDENCE BASED COPING STRATEGIES TO PREVENT CYBERBULLYING: WHAT WORKS?

Coping Strategies in Relation to Health Outcomes: What Do We Know?

A classical framework for evaluating processes of coping with stressful events is Lazarus and Folkman's (1984) Transactional Model of Stress and Coping. It emphasizes the importance of a cognitive judgement or subjective perception, which in turn impacts how individuals cope with a stressful situation. The model conceptualizes coping efforts along two dimensions: (a) problem-oriented or active coping strategies, and (b) emotion-oriented or passive coping strategies. Active strategies are geared to solving the problem and hence to decrease the stress, whereas passive strategies are geared to control the stress by cognitively reinterpreting the problem, for example by readjusting the perception of the problem, by making positive comparisons, and by putting the problem into perspective (Lazarus & Folkman, 1984). Other passive strategies include avoidance or distancing oneself from the problem through, for example, substance use.

Coping strategies have differential impacts on health (Lazarus & Folkman, 1984; Lazarus, 1999). Numerous studies have investigated the relationship between coping and health related problems. It has consistently been found that active strategies positively impact health: being negatively related to depressive symptoms and health complaints. In contrast, emotional coping has been found to negatively impact health, as they do not function to change a problematic situation or remove the actual stressor (Folkman, Lazarus, Gruen, & DeLongis, 1986; Garnefski, Pannebakker, Ruchlewska, & Kraaij, 2003; Lechner, Bolman, & van Dalen, 2007;

Moos & Holahan, 2007; Stanton, Reverson, & Tennen, 2007; Völlink, Bolman, Eppingbroek, & Dehue, 2013; Ybarra, Diener-West, & Leaf, 2007).

Effectivity of Coping Strategies: Personality Traits and Context

Although coping is distinguished from personality characteristics, it can be seen as a trait or disposition based on personality characteristics (Carver & Schreier, 1994; Moos & Holahan, 2003). Indeed, individuals who generally use problem-focused coping less often use emotion-focused strategies (Nielsen & Knardahl, 2014). Concurrent research in biology and epidemiology has shown that some personality dispositions like optimism are linked to coping. Optimism is defined as the tendency to have positive rather than negative generalized expectancies for outcomes. These expectancies are rather stable over time and across situations (Carver & Connor-Smith, 2010). According to the Cognitive Activation Theory of Stress (CATS), coping strategies are selected based on previous learning as well on expectations of the outcomes. Individuals who generally have a positive outcome expectation use problem-focused coping strategies, whereas individuals who generally have the perception that situations are not controllable consider their actions as useless or as actions which decrease chances on positive outcomes. So, they expect no relation or a negative relation between actions and outcomes (Ursin & Eriksen, 2010). Thus it seems that optimism and related outcome expectancies and controllability of the situation influence the coping strategies.

Do We Have Enough Insight in Effectiveness of Coping Strategies to Advise Cyberbully Victims?

From the above it can be concluded that emotion-focused coping strategies lead to more health problems than problem-focused strategies, and that emotion-focused strategies are used in situations which are perceived as uncontrollable.

Coping in the context of cyberbullying has received a substantial amount of attention, because ineffective coping strategies appear to maintain cyber victimization (Skrzypiec, Slee, Murray-Harvey, & Pereira, 2011). Vandebosch and Van Cleemput (2009) found that contextual features, such as the kind of relationship between victim and perpetrator, are relevant for the emotional impact of the cyberbullying experience. So it seems plausible that this relationship affects the effectiveness of the coping strategy. One important aspect regarding bullying is the power differential between bully and victim and the inferior position of victims (Einarsen, Hoel, Zapf, & Cooper, 2011; Leymann, 1996; Smith & Brain, 2000; Smith et al., 2008), which may implicate that victims of bullying perceive their situation as less controllable. Hence, it may be expected that they often use emotion-focused coping strategies. This has been confirmed in the literature. Victims of bullying at work tend to use emotion-focused coping strategies (Djurkovic, McCormack, & Casimir, 2005; Hogh & Dofradottir, 2001; Ólafsson & Jóhannsdóttir, 2004), victimized CYP of traditional bullying tend to use passive or avoidance styles and are less likely to use active styles (Skrzypiec, et al., 2011; Waasdorp & Bradshaw, 2011), and victims of cyberbullying use less problem-focused coping strategies (Cassidy & Taylor, 2005), more depressive coping (Völlink, Bolman, Dehue, & Jacobs, 2013), and are less likely to seek social support, compared to other strategies (Dehue, Bolman, & Völlink, 2008;

Kowalski, Limber, & Agatston, 2008; Parris, Varjas, Meyers, & Cutts, 2011; Slonje, Smith, & Frisén, 2013).

In some cases however, problem-focused strategies are not successful (Perren et al., 2012). In one study, young people were asked which strategies against victimization of cyberbullying were effective and which were not. The study showed that victims used technical solutions like blocking contacts, sought social support, and confronted their bullies online, which are active strategies through which the problem should be solved. However, they also indicated that these strategies are not effective (Machackova, Cerna, Sevcikova, Dedkova, & Daneback, 2013). Thus, problem-focused coping strategies are not always to the benefit of victims. This is in line with CATS and Zapf and Gross (2001) suggesting that emotion-focused strategies are more suitable when control over the situation is lacking. This was corroborated in the work of Dehue et al., (2008) and Parris et al., (2011), in which students recommended strategies like distancing and ignoring. In the study of Machackova et al., (2013), victims indeed rated ignoring as emotionally helpful. Machackova et al. (2013) and Parris et al., (2011) concluded that ignoring might be a good solution for victims of cyberbullying and they recommend taking such “inaction” into account when elaborating on coping strategies against cyberbullying.

These results suggest that more research is needed to effectively advise cyberbully victims, as knowledge regarding the effectiveness of these strategies in cases of cyberbullying is still scarce. This is partially due to the lack of instruments for the assessment of coping strategies in the context of cyberbullying. Almost all studies investigating coping with cyberbullying used instruments which measure coping in stressful situations. Cyberbullying however has some specific features which are distinguished from stressful situations in general. Recently, new instruments have been developed to measure coping with cyberbullying, like the Cyberbullying Coping Questionnaire (CCQ) (Jacobs, Völlink, Dehue, & Lechner, 2015), and the Coping with Cyberbullying Questionnaire (CWCBQ) (Sticca et al., 2015).

Is It Possible to Advise Children and Young People?

Although more research is obviously needed, we cannot afford to wait as children and young people need help and advice. We have to base the advice for these young people on the most conclusive knowledge we have so far. Seeking social support from parents and peers, for example, is proven to be an effective way to prevent victimization and to control negative outcomes (Kowalski et al., 2014). Since CYP tend to keep silent (Tokunaga, 2010), they have to be convinced to inform their parents and peers when they are online victimized.

Advice for CYP may be based on determinants of cyber victimization as described above. The way of using the Internet appears to be an important determinant. Victims should learn how to behave on the Internet (Kowalski et al., 2014) and how to use the Internet in a safe and secure manner (Álvarez-García et al., 2015; Barlińska, Szuster, & Winiewski, 2013; Chang et al., 2015; Helweg-Larsen et al., 2012; Hinduja & Patchin, 2009; Mishna et al., 2012; Walrave & Heirman, 2011). Another important determinant is the control over emotions whilst using the Internet (Hemhill & Heerde, 2014; Vazsonyi et al., 2012). Moreover, as described above, providing training to increase social skills (Navarro et al., 2012) should also be effective. In the meantime, we have to try to influence their outcome expectations, which are determinants of coping behaviour (Ursin & Eriksen, 2010), as stated above.

For some advice, positive effects are plausible. Since evaluative thoughts mediate the relation between the interpretation of the situation and the emotional, behavioral, and inferential reactions to these events (Ellis, 2001; Ringrose, & Nijenhuis, 1986), awareness in the relation between a thought, feeling, and behavior should be raised, and irrational thoughts should be replaced by more rational thoughts.

Is It Necessary to Tailor Advice for Children and Young People?

Advice cannot be effective if it does not fit the personality dispositions, outcome expectancies, and knowledge of the receiver. Prior research has shown that CYP who are resilient, tend towards a problem-solving approach of coping, such as deleting unwelcome messages and blocking contacts in the context of cyberbullying, or seeking social support from peers and adults (D'Haenens, Vandoninck, & Donoso, 2013; Hunter, Boyle, & Warden, 2004; Machmutow, Perren, Sticca, & Alsaker, 2012; Matsunaga, 2011). It is also suggested that optimism, related outcome expectancies, and controllability of the situation influence the use of coping strategies (Carver & Connor-Smith, 2010; Ursin & Eriksen, 2010). Also, as mentioned above, traditional bullying is one of the strongest predictors for cyberbullying, and CYP can be involved in bullying as a passive victim, a bully, a bully/victim, and a bystander. Bully/victims are victims who retaliate by bullying, probably because they expect positive outcomes of this behavior. Moreover, in evaluating their intervention, Jacobs, Völlink, Dehue, and Lechner, (2014a) suggest that lower-educated cyberbully victims aged between 12-15 years old do not like to read a lot. Hence, victims should be offered intervention strategies based on individual needs (Patchin & Hinduja, 2011).

Huang and Chou (2010) found that the most frequent behavior reported by victims and cyberbullies was threatening and harassment, followed by making jokes about someone or making fun of someone, and lastly spreading rumors. The impact of the cyberbullying experience and the kind of emotion that is evoked may depend on specific bullying behavior. For example, threats might evoke anxiety whereas making jokes and name-calling might evoke anger, and placing humiliating photos and video clips might evoke shame. These different emotions require specific coping strategies. In line with Vandebosch and Van Cleemput (2009), effectivity of coping strategies also depends on contextual features like the relationship between victim and perpetrator.

Therefore, it is of utmost importance that information and advice in interventions is tailored. Important factors for tailoring are personality features, educational level and age, (cyber)bullying behaviors, contextual features, and roles of involvement in (cyber)bullying. Tailoring is possible through the use of web-based interventions. Research has shown that computer-tailored messages are perceived as more personal and relevant than general information, are more often read, saved, remembered, and discussed (Brug, Oenema, & Campbell, 2003), and are more effective, that is, result in more improvement in behavior, than general information (Krebs, Prochaska, & Rossi, 2010).

STAND-ALONE ICT INTERVENTIONS

Stand-Alone ICT Interventions to Prevent and Combat Cyberbullying: Theoretical and Evidence-Based Methods

Cyberbullying intervention resources can be divided into school-based and stand-alone interventions. School-based interventions are programs which are used in classrooms or whole schools, for example *Medienhelden* (Wölfer et al., 2014), *ConRed* (Ortega-Ruiz, Del Rey, & Casas, 2012), *Let's not fall in a trap* (Menesini, Nocentini, & Palladino, 2012), *Cyber friendly schools project* (Cross, Roberts, & Slee, 2013), and *Survivors* (Amse, 2014), containing for example; lessons, videos, presentations, discussions, and workshops. Most of the programs, however, are lacking scientific merit, due to a lack of inclusion of a follow up measure and a failure to use random assignment at the classroom or school level and the effectiveness is not impressive (Cioppa, O'Neil, & Graig, 2015).

Stand-alone interventions are programs that can be used independently of schools and classrooms, at the time and place of benefit to the user. Most stand-alone interventions are psycho-educational websites. A host of these sites are provided, containing tips, advice, and recommendations regarding cyberbullying. The advantage is that the users can select items they need. The problem is, however, that many of these materials and programs, whilst well intentioned, do not have a theoretical base, nor has the effectiveness of their materials been investigated (Völlink, Dehue, Mc Guckin, & Jacobs, 2016). There are some exceptions which will be described below. These stand-alone interventions are tailored to personality characteristics and needs and are based on theory and tested on effectivity.

FearNot (Sapouna, Enz, Samaras, & Wolke, 2015) is a game in which the participants have an active role, in that they are asked to help the victims. The game shows them the effects of their support. The intervention consists of a virtual simulation of a primary school environment in which virtual characters can take the role of a bully, victim, bully-assistant, victim-defender, or bystander. It is based on the proven educational benefits of role-playing as a form of experiential learning, a process in which experience is transformed in acquired knowledge. Role-playing is proven to be particularly effective with social and emotional difficulties in school (Sapouna et al., 2015).

Online Pestkopenstoppen (Jacobs, Völlink, Dehue, & Lechner, 2014b) or "Stop the Bully Online" has been developed for victims and bully/victims of (cyber)bullying, and contains three online tailored modules. The intervention is based on principles of Rational Emotive (Behavioral) Therapy (RE(B)T) (Ellis, 2001). The first module aims to teach participants about the connection between thoughts and behaviour. In the second module participants learn effective coping strategies in response to cyberbullying, and in the third module participants learn to use the Internet in a safe and secure manner. This intervention is developed according to the Intervention Mapping protocol, which consists of six steps that can be used as an iterative process for theory- and evidence-based development of health promotion interventions. The aforementioned needs assessment is the first step, the determinants influencing victimization are needed for the second step, and the selection of theory-based intervention methods contains the third step. *Online Pestkopenstoppen* uses several theoretical and evidence-based methods like modelling by introducing role models, demonstrating how to act, repeated exposure, consciousness raising, guided practice, and persuasive communication (Jacobs et al., 2014b).

Friendly Attac (Van Cleemput et al., 2015) is a serious game for bystanders of bullying. It is an online, one-player puzzle game with a virtual character and bullying experience scenarios in which players can choose several behavioural alternatives, like ignoring the bully and standing up for the victim. Like *Pestkoppenstoppen*, it is developed according to the Intervention Mapping protocol, and uses modelling and active learning for behavior change. Moreover, the intervention is based on a narrative, which is developed according to several theoretical statements. For example, the statement that participants who are more engaged in a story show more story-consistent beliefs and opinions, and that this “transportation” is positively predicted by story-line appeal, quality of production, and by unobtrusiveness of persuasive subtext (Van Cleemput et al., 2015).

The Empathic Virtual Buddy (Van Der Zwaan, 2014) automates the one-to-one online counseling between victimized children and the virtual buddy, the latter providing emotional support and practical advice on how to deal with the situation. The intervention is developed according to a conceptual communication model that is based on the literature on social support. The model specifies the content of conversations in which social support is provided, and contains several types of social support, such as sympathy, compliments, advice, encouragement, and technical support. The model also specifies the structure and sequence, or pattern, of conversations (question and answer).

The Reporting Button is an intervention specifically aimed at combatting cyberbullying and buffering the negative effects in a short time frame. The visitor of the website is provided with a button that can be installed on the computer and that can then be used to report an incident of cyberbullying. The site also provides information on how to prevent cyberbullying and what to do if it occurs. Free telephone numbers, a link to the bullying-website Pestweb (<http://pestweb.nl>), and a link to chat sessions with co-workers of the bullying-website is provided. The site also contains information on how to report cyberbullying incidents to the police.

Stand-Alone ICT Interventions: Important Conditions to Let It Work

The paragraphs above refer to several useful conditions to let a stand-alone intervention work. First of all, the intervention should be tailored on relevant needs and determinants, like personality dispositions, knowledge, emotions, and outcome expectancies of the target group. However, the number of questionnaires necessary for tailoring should be limited, and questionnaires should be kept as short as possible (Edwards et al., 2009; Jacobs et al., 2014a).

The content is an important condition for interventions to be successful. Appreciation of the materials seems to depend on the novelty and on the helpfulness of the information. Therefore information should be new and related to solving examples of specific cyberbullying situations, and less attention should be given to abstract concepts (e.g., recognizing, disputing, and replacing irrational thoughts (Jacobs et al., 2014b)). In the meantime, to keep the participants motivated, the information provided should be limited and not too complex (Baumeister, 2014; Brouwer et al., 2009; Jacobs et al., 2014a). Another possibility to reach the target population is the gamification of the online ICT-intervention. Nacke, Bateman, and Mandryk (2014) and Yee, Ducheneaut, and Nelson (2012) distinguish seven gamer types that differ in the features that make games interesting: the achiever, the conqueror, the daredevil, the mastermind, the seeker, the socializer, and the survivor. The achiever, for example, is goal-

oriented and gets satisfaction from completing tasks, whereas the seeker is more curious, enjoys exploring things, and discovering new situations.

Also the structure is an important condition. Online interventions should have an easy login procedure, should be clearly structured with a simple design (Brouwer et al., 2009; Schneider, van Osch, Schulz, Kremers, & de Vries, 2012), should have a progress bar and the option to partially complete questionnaires, and the choice to continue at a more convenient time (Schneider et al., 2012). Moreover, since re-visits are relatively uncommon (Schulz et al., 2014) and interest in returning to intervention websites decreases over time (Gustafson et al., 2001), participants should be able to select and use intervention components immediately (Jacobs et al., 2014a) or should be able to complete the intervention by returning to the website a number of times. Sessions should be short; website visits should not be longer than 17 minutes (Verheijden, Jans, & Hildebrandt, 2008). Moreover, the online world of adolescents is subject to change rapidly, so websites should be updated on a regular basis (Leslie, Marshall, Owen, & Bauman, 2005).

In evaluating Online Pestkoppenstoppen, Jacobs et al. (2014a) found that many low-educated adolescents lack the motivation and discipline to complete their intervention on an individual basis. They concluded that this low-educated target group needs more guidance and structure in using the intervention. Adding face-to-face elements with parents or teachers to stimulate engagement might also strongly increase retention.

Although stand-alone ICT interventions are to the benefit of adolescents because of tailoring possibilities and the possibility of completing the intervention at convenient moments and places, there are many aspects that should be taken into account to make them successful and effective.

“OLD WINE, NEW BOTTLES”: THE CHALLENGE OF NEW TECHNOLOGY

Each period of technological advancement brings with it excitement and opportunity whilst also being accompanied by worry and concern regarding the risk and potential harm posed to society - particularly its young. With the arrival of television there was concern that children would be exposed to unsuitable content, that they would damage their eyes by sitting too close to the television screen, and that their academic and intellectual development would be impaired and hindered. Similarly, widespread access to video games (especially violent ones) in the 1990s raised many of the same concerns. Historically, there were many other technological advances to create anxiety. Cassette players with earphones might have damaged the hearing of a generation. Before that, there was the supposed danger of records being played backwards to communicate satanic messages. In the 1800s, there was worry about the problem of students becoming overly reliant on paper and neglecting to learn how to properly use a slate and chalk, for when paper would inevitably be in short supply. In the first part of the 21st century, the focus has been firmly on Internet access, and in particular, the risks posed to children and young people (CYP). This brief look at historical advances and the challenges of technological progress begs the question - why do we always feel the need to “reinvent the wheel”? Just as those people who were alive at the beginning of the agricultural revolution or the industrial revolution faced challenges, those of us living through the “digital age” face new and previously unimaginable tests. Can we not, in a Piagetian manner, just assimilate the digital challenges into existing schemas - like the schema we all have for “coping” with other, more familiar stressors? However, in saying this, it must be acknowledged that the online world poses unique challenges.

Staksrud and Livingstone (2009) make a distinction between different types of risks faced online, including: content risks (receiving unwanted or inappropriate mass communication); contact risks (participation in risky communication); and conduct risks (contributing to risky content or contact). These types of risk can be further broken down into risk categories depending on their commercial-, aggression-, sexual- or value-based nature. Bullying would most likely fall under the sub-types of aggressive conduct (for the perpetrator) and aggressive contact (for the targeted individual). Whilst cyberbullying is certainly considered a risk to CYP, it does not always lead to psychological harm. Indeed, harm is not an inevitable outcome of risky behaviour. Harmful effects of cyberbullying can be mediated and moderated by variables such as the severity of the online content, the public access to the abusive content, and, importantly, the coping strategies used by those targeted and those around them, such as parents and teachers. Although people have always found ways to cope with risks posed, it is important to keep in mind that these strategies are not always advantageous.

Just like adults, modern CYP will use both adaptive and maladaptive coping strategies. However, unfortunately their developmental stage does not always work in their favour. A frontal cortex that is not fully matured to aid reasoned and considered decision making and to support a capacity to foresee consequences can lead to impulsive reactions. Furthermore, the invincibility fable (belief that one is invulnerable to risk: e.g., Berger, 2011) which is characteristic of this age group is not associated with cautious risk assessment, and indeed may put teenagers at increased risk for exploitation online. For instance, a teenage boy who shares intimate photos of himself with his girlfriend through private messaging may underestimate both the risk and potential personal impact of such content being shared with others. Furthermore, upon discovering that such personal material has been widely disseminated with his schoolmates, he may respond instantly and aggressively, serving to escalate an already precarious situation. So, this begs the question: how can we best support CYP to deal with aggression and bullying online?

In the current chapter, both of the terms cyberbullying and cyber aggression (see Corcoran, Mc Guckin & Prentice [2015] for examination of cyberbullying and cyber aggression) will be discussed. In the current context, both refer to peer-to-peer abuse in a cyber setting. The purpose of the current chapter is to review the knowledge on coping strategies in relation to cyber victimization, and to offer direction regarding the next steps needed to better equip young Internet users to protect themselves online. The work of Kochenderfer-Ladd and Skinner (2002) emphasises the importance of exercising caution when assessing the effects of coping strategies, given that poor selection of coping may increase risk. Therefore, we will review the relevant literature examining the concepts of stress and coping before looking more closely at the literature which pertains to individual coping with bullying specifically. Furthermore, this chapter will review some of the societal or community-based efforts to cope with bullying and victimization, such as intervention programmes, national and international guidelines, and proposed legislative changes. Ultimately we will argue that, although the cyber world entails some daunting challenges, this is not the first point in history at which humans have felt threatened by new technology. Thus we should consider what we “already know” about effective coping and strive to further our empirical knowledge.

COPING WITH PSYCHOLOGICAL DISTRESS

Coping can be defined as “. . . the things that people do to avoid being harmed by life strains” (Pearlin & Schooler, 1978, p. 2). That is coping includes the efforts people make to prevent, avoid, or control emotional distress. According to Pearlin and Schooler (1978) coping is a broad term and coping resources include behaviours, cognitions, and perceptions which can prove useful when one is faced with stressors or problems. Thus, when considering aggressive victimization in cyberspace, different individuals may have different behavioural responses, differing thoughts and emotions regarding the incident, and indeed may perceive the aggression as more or less harmful, intentional, or severe than another individual would.

Lazarus and Folkman (1984) define coping as “. . . constantly changing cognitive and behavioural efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person” (p. 141) which suggests that coping strategies are employed when there are demands which exceed an individual's resources and furthermore, coping includes attempts to manage these demands. Thus, the effectiveness of coping strategies is not integral to recognising the response as coping. For example, externalising one's distress through stamping on the Smartphone which delivered aggressive, hurtful content, may not be adaptive, but it may still be considered a coping response. Furthermore, where aggressive behaviours online are not considered to be especially taxing or distressing, perhaps coping strategies are unnecessary. It is important to be mindful of the great variations in individual responses to cyber aggression. Whilst for Jane, an embarrassing photo shared on a social media platform may be highly distressing, it may not bother Sophie in the least. However, how Jane and Sophie respond to (or “cope with”) the sharing of such a photo may have important implications for how the perpetrator(s) proceed(s) thereafter. Furthermore, coping strategies may include efforts which are effective, ineffective, or indeed harmful in terms of protecting physical and psychological well-being or in stopping the aggression from recurring. Indeed, Carr (2011) suggests that different coping styles include strategies which can be functional or dysfunctional. For instance, although physical exercise may constitute functional emotion-focused coping, aggressive acts may constitute dysfunctional emotion-focused coping.

Lazarus and Folkman (1984) suggest that coping functions defined in relation to specific situations are more situation-specific, and therefore, it is important to examine coping in relation to traditional bullying and cyber aggression problems in a situation-specific manner. In other words, it is important that researchers examine coping with cyber aggression by looking at real experiences of coping with such victimization or by examining participants' suggested coping strategies in response to victimization, as opposed to studying general coping styles. Folkman and Lazarus (1980) describe how “. . . coping efforts serve two main functions: the management or alteration of the person-environment relationship that is the source of stress (problem-focused coping) and the regulation of stressful emotions (emotion-focused coping)” (p. 223). That is, when faced with aggression on a social media platform, the victimised individual might choose a strategy that is problem-focused, such as cancelling their account, blocking the aggressor, or reporting the abusive content to the provider. Alternatively, the targeted person may choose to spend time with friends who can help to take their mind off the upsetting incident, or they might binge eat chocolate and sweets so as to divert their attention to some transitory pleasure in an effort to regulate distressing emotions. A person may also employ both problem-focused and emotion-focused strategies. Appraisal theory suggests that

emotion-focused strategies are generally used when a situation is considered to be too difficult to rectify or improve, whilst problem-focused coping is generally employed when one feels the situation can be dealt with effectively (Folkman & Lazarus, 1980; Lazarus & Folkman, 1984). One of the difficulties of dealing with cyber aggression is that without knowledge of appropriate coping responses, victimization can seem overwhelming and unmanageable.

According to Roth and Cohen (1986) coping can be categorised as approach or avoidance strategies, that is, “. . . cognitive and emotional activity that is orientated either toward or away from threat” (p. 813). Roth and Cohen (1986) suggest that avoidance can be adaptive initially when an individual has limited emotional resources and can be appropriate when the situation is beyond one's control. By contrast, approach strategies are appropriate when there is the possibility to control the source of stress. Therefore, when a teenager is overwhelmed by cyber aggression and does not have the tools or social support to stop the abusive behaviour, it may be adaptive in the short term to avoid social media. However, over time this strategy could be isolating and ultimately harmful. In addition, Lazarus and Folkman (1984) argue that how we cope can be determined by a range of factors including physical health, psychological factors such as positive beliefs, and personal competencies such as social skills. Thus, CYP who are victimised via social media may be better equipped to cope in an effective manner to stop the problem and to buffer the negative psychological effects, if they feel well physically, have high self-efficacy with regard to their ability to deal with the issue at hand, and can garner support from friends, teachers, and family.

When examining how people deal with cyber victimization, it is evident from this brief review of the general coping literature that coping strategies include thoughts and behaviours which may help or hinder both success in ending the victimization and success in protecting psychological well-being. In their literature review of coping with cyberbullying, Perren et al. (2012a, 2012b) make this distinction between combating cyber victimization and buffering the negative effects. In this field we are faced with many challenges. As Coolican (2007) highlights, there is no guarantee that a solution to a problem will succeed every time it is tried, or that it will be successful with specific individuals. Each individual will behave in different ways, even though external circumstances can sometimes be almost identical. As the old adage goes, in psychology we deal with people, not chemicals - that is, we are trying to do important science but using dirty test-tubes. Taking again the example of Jane and Sophie; both are teenage girls who have been “victim” to an embarrassing photo posted online. Yet, each girl will have their own unique set of situational components (e.g., concurrent stresses, appraisal of the situation), self-related components (e.g., internal locus of control, psychological maturity), supports (e.g., family support, community), and strategies (e.g., preferred coping responses) which can impact how they experience and deal with the situation (Schlossberg, Waters, & Goodman, 1995). In other words, each person will bring a unique array of assets and limitations to every experience; making it exceptionally difficult for researchers to provide a generic set of coping strategies for a wide array of potential victim experiences. Despite such real issues, we are tasked with supporting CYP to make better decisions in response to online risk, and therefore, we must start by examining how CYP respond to victimization and what we know about the effectiveness of such responses in terms of (a) combating cyber victimization and (b) buffering the negative effects. Therefore, the next section reviews the literature regarding how CYP cope with peer-to-peer bullying and aggression.

COPING WITH TRADITIONAL BULLYING: WHAT WORKS?

When exploring how individuals cope with bullying, researchers have used a variety of methods including retrospective accounts of victimization, observation, self-report questionnaires, and interviews. Whilst some researchers have assessed victims' coping styles in relation to coping with daily stress (e.g., Escobar, Fernández-Baena, Miranda, Trianes, & Cowie, 2011), others have utilised hypothetical scenarios (e.g., Andreou, 2001), and then again other studies examined how victims coped with real experiences of victimization (e.g., Frisén, Hasselblad, & Holmqvist, 2012). Although varied methods are useful in terms of enhancing our knowledge of how individuals respond to victimization, it is difficult to accurately compare findings across the research. The literature has also highlighted that coping styles are selected based on different factors such as the types of bullying one is faced with (Kanetsuna, Smith, & Morita, 2006; Kristensen & Smith, 2003; Murray-Harvey, Skrzypiec, & Slee, 2012), appraising the situation as either a threat or challenge (Hunter & Boyle, 2004), environmental aspects of the situation such as the school environment (Murray-Harvey et al., 2012), and personal factors like one's capability to regulate emotions (Kochenderfer-Ladd, 2004; Spence, De Young, Toon, & Bond, 2009). Thus it can be difficult to find a coherent thread in the literature, which is also limited by a lack of focus on the effectiveness of coping in stopping the victimization or reducing its negative consequences.

Despite such limitations it is evident that some trends emerge across studies. For example, it seems that females are more inclined to seek social support than males (Hunter & Boyle, 2004; Kristensen & Smith, 2003; Murray-Harvey et al., 2012; Naylor, Cowie, & del Ray, 2001; Olafsen & Viemerö, 2000; Smith & Shu, 2000), and this may in fact be an effective strategy (Kochenderfer-Ladd, 2004; Smith, Talamelli, Cowie, Naylor, & Chauhan, 2004). Also, similar to more general psychological literature, females seem more inclined to engage in internalising coping (Kristensen & Smith, 2003), whilst males tend to engage in externalising coping (Kochenderfer-Ladd & Skinner, 2002; Kristensen & Smith, 2003) and are quicker to retaliate (Smith & Shu, 2000). In addition, those who are both perpetrators of bullying and are victimized tend to engage in retaliation (Pateraki & Houndoumadi, 2001) and also favour externalising strategies (Kristensen & Smith, 2003). Although there is a lack of focus on the efficacy of various coping responses, there is in fact some knowledge regarding strategies which seem to be useful in terms of stopping victimization and buffering its negative effects, and strategies which seem to be ineffective or even counter-productive.

For instance, it seems that, in general, retaliation and aggressive coping are not to be encouraged as these strategies can serve to escalate and prolong bullying (Mahady Wilton, Craig, & Pepler, 2000; Spence et al., 2009) and can have negative psychological consequences such as depression (Mahady Wilton et al., 2000). Avoidance, distancing, or passive coping; responses which could perhaps be symbolised by the ostrich with its head in the sand, are also undesirable coping styles (Escobar et al., 2011; Hunter & Boyle, 2004; Kochenderfer-Ladd & Skinner, 2002; Mahady Wilton et al., 2000; Murray-Harvey et al., 2012) with, for example, distancing being linked with greater risk of victimization (Kochenderfer-Ladd, 2004). By contrast, problem solving strategies have been found to de-escalate a bullying incident (Mahady Wilton et al., 2000) and active (rather than passive) problem-solving may be effective as it can allow for assertive behaviour. There is also some evidence that conflict resolution and seeking advice are associated with decreased victimization and internalising problems. However,

cyberbullying and aggression bring a host of new challenges which were not encountered when dealing with traditional bullying; such as the capacity to attack a targeted individual at any time of day or night from almost any location, the potentially global audience for abuse, the unique role of bystanders, the possibility to remain anonymous, and the difficulty in retrieving widely disseminated data. Thus, in 2016, we must ask whether we can use the existing knowledge to inform the coping strategies we recommend when facing traditional bullying, cyberbullying, or both. In other words, is cyberbullying really a case of “old wine, new bottles” (e.g., Li, 2007) or do we need to reinvent the wheel?

COPING WITH CYBERBULLYING AND AGGRESSION: A DIFFERENT BALL GAME

Similar to the literature which has focused on traditional bullying, studies of how CYP cope with cyber victimization indicate that researchers have used a variety of approaches, including self-report questionnaires and interviews, which again makes it difficult to compare studies and to identify effective coping strategies. However, the research to date has allowed for some useful insights. For example, it is apparent that there is general reluctance to report cyber victimization to adults (Hoff & Mitchell, 2009; Juvonen & Gross, 2008; Li, 2006; Smith et al., 2008). Perren et al. (2012a, 2012b) conducted a systematic literature review which focused on coping with cyberbullying among CYP. The review indicated that in a number of studies it has been found that there is a disinclination to consult adults for fear of losing technology-related privileges. In addition, they are concerned that parents might encourage them to ignore the problem or simply be unable to assist them due to lack of familiarity with cyberspace. Recent large scale research in an Irish context (Dooley & Fitzgerald, 2012) examined the psychological health of a large sample of adolescents and young adults. This study revealed that not only is bullying a predictor of increased depressive and anxiety symptoms, but the availability of at least “one good adult” (an adult who knows him/her personally and is available, particularly in times of need) was one of the strongest predictors of good mental health. This was associated with self-esteem, sense of belonging, and coping in response to difficulties. By contrast, the absence of such a person was significantly associated with the level of depression, suicide, and self-harm. This is particularly relevant to the literature indicating the reluctance of young people to confide in parents and teachers when confronted with online victimization. It seems that the perception of adults as ill-informed or reactionary in terms of taking away technology in effect removes a very important coping resource from young people. Not only do they lose the potentially useful practical assistance that an adult might provide, but the very comfort of knowing that there is “one good adult” on standby is eliminated. Whilst there is evidence to suggest that social support may benefit cyber victims (Machmutow, Perren, Sticca, & Alsaker, 2012), it seems that social support may worsen the situation for males, but may benefit females over time (Shelley & Craig, 2010). More gender-specific research is required to further explore this finding. It would also be useful to examine the role of bystanders in a cyber setting. Given the potential for bystanders to spread aggressive content very rapidly and widely it is worth examining how one might gain support from others online.

Technical coping strategies (i.e., strategies which require engagement with the Internet, with a device, or with a particular medium) may help to reduce a cyberbully's access to the victim. Furthermore, the capacity to save and reproduce online content can allow a victim to document evidence of aggression if support is required from school administrators, or the police. Price and Dalglish (2010) found that blocking an aggressor was reported to be the most effective online strategy. With technical coping in mind, researchers have suggested that more focus on education in relation to cyber safety may be beneficial (Juvonen & Gross, 2008; Yilmaz, 2011). However, it is important to remember that relying on technical strategies alone may leave young people vulnerable to ongoing abuse. Šléglová and Černá (2011) highlight that the effectiveness of technical strategies is partly dependent on support from administrators. For instance, if a young person reports upsetting activity on a social networking site, such as having a profile set up by an impersonator for malicious purposes, an action from the site administrators is required. In addition, blocking the phone number of a cyber aggressor does not preclude that person from creating a new account and recommencing negative contact. Thus, it is important to remember that there are limits to the effectiveness of technical coping alone and an arsenal of strategies would be desirable.

Although there is some evidence to suggest that seeking social support and utilising technical coping strategies can be effective, seeking revenge or retaliating seem not to be effective strategies in cyberspace as they neither reduce victimization (Shelley & Craig, 2010) nor combat depression (Machmutow et al., 2012). Taking a contrasting approach, the sometimes “head in the sand” response, such as passive coping, depressive coping (Völlink, Bolman, Dehue, & Jacobs, 2013), avoidance (Hoff & Mitchell, 2009), or helpless coping (Machmutow et al., 2012) also seem not to be desirable strategies. Indeed, recent research by Corcoran and Mc Guckin (2014) revealed that, similar to victimization by traditional or cyber victimization, recommending helpless coping as a response to cyber aggression (i.e., self-blame, passive inaction) was a predictor of increased depressive symptoms and reduced psychological well-being. By contrast, assertive coping, characterised by asking the bully why he/she is doing this, telling the bully to stop, and using technical strategies, was a weak, but significant predictor of increased psychological well-being. Overall, the small amount of evidence which examines the effectiveness of coping strategies in response to cyber victimization indicates some parallels with traditional victimization, with for instance, social support seeking showing some positive potential as a strategy and avoidant or aggressive coping appearing to be maladaptive responses. It is evident that more research is required in order to adequately assess the most useful strategies a young person can engage in as an individual when faced with cyber-based aggression. However, there has been a number of initiatives in the form of anti-cyberbullying programmes which aim to prevent and intervene with this form of aggression on a larger scale.

PREVENTION AND INTERVENTION: ANTI-BULLYING AND ANTI-CYBERBULLYING INITIATIVES

Not surprisingly, school-level efforts to cope with cyberbullying and cyber aggression have been informed by prior initiatives to combat traditional bullying. Mc Guckin and Corcoran (2016) emphasise the need to consider a number of important yardsticks when designing and/or

implementing an intervention for bullying and cyberbullying/cyber aggression. Principles of sound intervention include, for example: theoretical grounding; evidence-based practice; and clarification of what the proposed outcomes should be, such as reduced perpetration of, and victimization by, bullying and cyberbullying or cyber aggression. Existing traditional anti-bullying programmes are underpinned by a variety of different theories and philosophies such as focusing on positive bystander behaviour (Kiva: Kärnä et al., 2011), a zero tolerance response to bullying with importance placed on adult authority figures (Roland, Bru, Midthassel, & Vaaland, 2010), the Shared Concern Method (Pikas, 2002), restorative justice (Morrison, 2006), social skills training (DeRosier & Marcus, 2005), and peer support networks (Cowie & Olafsson, 2000).

For instance, in Finland the Kiva anti-bullying programme “. . . is predicated on the idea that a positive change in the behaviors of classmates can reduce the rewards gained by bullies and consequently their motivation to bully in the first place” (Kärnä et al., 2011, p. 313). The Kiva programme (Kärnä et al., 2011) was developed based upon the insights regarding the different participant roles of those directly involved in bullying and those who witness it. The purpose of the programme is to enhance the empathy, self-efficacy, and anti-bullying attitudes of bystanders so as to encourage pro-social responses upon witnessing bullying (Kärnä et al., 2011). Such an approach in which young people are empowered to respond to aggression in a pro-social manner could be useful in the cyber setting – an environment which is often lacking an adult presence. However, it would be important to ensure that efficacy is enhanced with appropriate strategies for helping.

Peer support networks (Cowie & Olafsson, 2000) offer an approach somewhat similar to the Kiva programme in that the peer group holds the power in terms of offering potential solutions. Cowie and Olafsson (2000) suggest that “One effective way of tapping the potential resource of the peer group comes from training selected young people in peer support” (p. 80). Citing Cowie and Sharp (1996), Cowie and Olafsson (2000) acknowledge three forms of peer interventions, namely: befriending, conflict resolution, and counselling-based approaches. Moreover, they suggest that these forms of peer support require: (a) a response to a request for help; (b) appropriate skills to support victims to find solutions; (c) adults who can supervise the network; and (d) the incorporation of non-punitive interventions. A peer support approach which tackles traditional bullying could be extended to also deal with cyber-based bullying and aggression, so long as there is adequate adult involvement and research informed strategies in response to victimization.

The “Zero” programme (Roland et al., 2010) takes an alternative approach, emphasising that bullying tends to occur when teacher control and support is lacking, thus creating an environment for such abuse to occur. Therefore, the Zero programme promotes an authoritative classroom leadership approach which can be implemented to inhibit behaviours such as humiliating peers as a bid for power, whilst striving to enhance social cohesion in the group. Thus, it is the adults who take responsibility for facilitating development of a climate in which bullying will be reduced. Within the Zero programme school personnel must address any divergence from the appropriate standards of behaviour in a respectful manner. Such a programme may not be appropriate in a cyber setting considering the lack of monitoring in many cyber environments. Although anti-bullying programmes tend to vary in terms of the theoretical underpinnings, a common component of many initiatives is the Whole School Approach which advocates involving the whole school and extended community to both prevent and intervene in bullying problems.

Rigby, Smith, and Pepler (2004) argue that “It is widely accepted that countering bullying requires a ‘whole school approach’ in which the elements and initiatives in a programme are carefully co-ordinated” (p. 2). The Olweus Bullying Prevention Program (OBPP: Olweus, 1993) is a whole school intervention programme which has been implemented and assessed on a large scale which targets bullying at the school-level (e.g., rules against bullying, involving parents), the classroom-level (e.g., holding meetings with students' parents, and posting and enforcing rules against bullying), the individual-level (e.g., student activities would be supervised and staff would be expected to intervene immediately upon witnessing bullying), and the community-level (e.g., helping to spread anti-bullying messages of best-practice throughout the community) (Olweus & Limber, 2010). In this way, bullying is regarded as a systemic problem, and therefore, it is addressed with a system-wide response. Farrington and Ttofi (2009) conducted a meta-analysis of studies which examined the effectiveness of school-based anti-bullying programmes. Elements associated with reduced bullying behaviour included a whole-school anti-bullying policy. Importantly, programmes which took their philosophy from Olweus were found to be most effective. However, a whole school anti-bullying policy was not found to be an important factor in reducing victimization. In fact, the meta-analysis highlighted the complexity of countering bullying in schools as different programme components were significant predictors of reducing victimization and reducing perpetration. So, does it make sense to roll out the same approaches to tackle cyber-based bullying and aggression? Perhaps there is some rationale for doing so, as many studies have highlighted an overlap across the two forms of aggression with the same individuals involved in both forms (e.g., Juvonen & Gross, 2008; Riebel, Jäger, & Fischer, 2009). However, once again it is important to consider the unique characteristics of cyberspace and it is vital that practitioners do not intervene in a way that ultimately does more harm than good.

Menesini, Palladino, and Nocentini (2015) argue that, considering the established overlap between traditional bullying and cyber forms of bullying, it is sensible to extend existing anti-bullying programmes to address cyberbullying. However, they too recognise that cyberspace has specific characteristics which do not pertain to traditional bullying. They have evaluated a programme called “Noncadiamointrappola!” (“Let’s not fall into the trap”) which aims to counter both forms of bullying and to promote positive use of technology. Displaying some parallels with Kiva and peer-support efforts, their programme has a pro-social approach, with provision of online support, promotion of positive cyber behaviours, and involvement of peers as educators in both physical and cyber settings. The first edition of the programme (2009/2010) was reported to have moderate positive effects. However, a stronger impact was found following a number of adaptations such as: equal emphasis on both bullying and cyberbullying; more focus on the bystander and victim roles; consideration given to coping strategies; peer-led face-to-face activities; and greater emphasis on the ecological approach where teacher support of class activities is emphasised. It is evident that this programme has a broad scope. Compared with control participants, the experimental group displayed reduced bullying, victimisation, and cyber victimisation. In addition, experimental participants had an increased tendency towards adaptive/desirable coping strategies and showed reduced maladaptive coping. Menesini et al. (2015) state that approach coping styles make bystander defending more likely, whilst empathy and anti-bullying attitudes are associated with increased bystander intervention. They also emphasise the need to focus not only on developing individual attitudes and coping styles, but also the importance of addressing the group as a whole. In the third stage of development, some additional emphasis was placed on new components, such as cooperative

work with increased consideration given to empathy and problem solving. More attention was also given to victim and bystander perspectives so as to show how change can be achieved. Showing consideration for the whole school approach, the programme included an ecological perspective (i.e., a school-wide approach). Overall, a significant decline in bullying, victimisation, cyberbullying, and cyber victimisation was found for the experimental participants compared to the controls. Although the effect size was not very strong, a programme such as this appears to meet the criteria that are important if we are to achieve what Mc Guckin and Corcoran (2016) emphasise as important: anti-cyberbullying programmes that are theoretically informed, methodologically robust, and empirically supported. Although there is relatively little evidence to date of the effectiveness of interventions and programmes which target cyberbullying specifically, there has been a number of international EU-funded initiatives (e.g., CyberTraining, CT4P, and COST IS0801 - see below) which have sought to develop educational tools and inform policy and practice through research, so as to counter online aggression.

CROSS-NATIONAL COLLABORATION: FORGING AHEAD IN THE BEST INTERESTS OF THE “ALWAYS-ON GENERATION”

In an ideal world there would be a wealth of knowledge in terms of how CYP cope effectively with cyber victimization and plenty of evidence regarding best practice in terms of intervening to protect children and adolescents online. However, there is little clarity regarding the best coping strategies and a paucity of robust research such as that provided by Menesini et al. (2015) detailing the effectiveness of anti-cyberbullying programmes and their components. We do not live in an ideal world, and we simply cannot wait until we have an abundance of evidence before we attempt to guide policy and practice so as to protect young Internet users. In order to advance knowledge about the nature of cyber-based aggression and bullying, and ultimately to facilitate development of better policy-making and practice, the European Union has funded a number of cross-national collaborations with important research and resource outputs.

The CyberTraining project (funded by the EU Lifelong Learning Programme: see Mora-Merchan & Jäger, 2011) culminated in a research-based training manual on cyberbullying. The manual provided a broad overview of the topic of cyberbullying, its nature and prevalence in Europe, approaches to countering cyberbullying, and best practice. The purpose of the project was also to provide practical guidance and resources for trainers working with the various target groups including school students, parents, teachers, as well as other professionals. Following the CyberTraining project, the CyberTraining for Parents (CT4P) was undertaken. The CT4P initiative sought to develop a more focused output aimed at training parents to address cyber safety and also to assist coping with cyberbullying. Specifically, outputs from CT4P included “face-to-face” training courses, self-directed online courses for trainers, and moderated online courses for parents. Through its initial development and implementation, many of the principles that we outlined above can be seen in action in the CT4P project. The project partly extended the material developed by the CyberTraining initiative, with the purpose of educating parents on ICT and Internet safety, the nature of cyberbullying, its prevalence and effects, legal

considerations at a national and international level, as well as strategies for preventing and countering cyberbullying.

Although the COST Action IS0801 (Cyberbullying: coping with negative and enhancing positive uses of new technologies, in relationships in educational settings: <https://sites.google.com/site/costis0801/>) led by Peter Smith, did not lead directly to an educational tool to be used in training, or a specific anti-cyberbullying programme, it made a very important contribution to many aspects of cyberbullying research and ultimately to prevention/intervention efforts. The Action allowed for collaboration among researchers and practitioners from the fields of traditional bullying, law, and telecommunications providers so as to advance the current knowledge on cyberbullying. Working groups were established in order to address specific aspects, such as: conceptualisation and definitional concerns; provision of national guidelines; reviewing knowledge on coping with cyberbullying; legal considerations and input telecommunication companies and service providers; and positive uses of new technologies. Not only did the Action facilitate the production and dissemination of new knowledge and research, it provided funding to facilitate development of research capacity among early stage researchers. Although such initiatives contribute greatly to current understanding of how “we” (researchers, psychologists, parents, teachers, government staff) can best cope with cyber-based bullying and aggression, some would argue that the only way to eliminate cyber aggression is to prosecute perpetrators. As a result, there are places in the world where traditional bullying and cyberbullying legislation has already been created, and there are currently many countries where there is hot debate as to whether this is the best way of coping with cyberbullies (e.g., Purdy & Mc Guckin, 2013).

POLICING THE WILD WEST: IS CYBERBULLYING LEGISLATION THE ANSWER?

Producing legislation to crack down on cyberbullying and trolling is sometimes likened to efforts to police the Wild West (Corcoran, Frazer, & Mc Guckin, 2015). However, bullying and cyberbullying offences have been criminalised in some parts of the world, and it is often the case that such legislation is introduced following tragic deaths by suicide following prolonged victimization. For example, in California, USA, Seth’s Law (2011: <http://e-lobbyist.com/gaits/text/354065>) pertains to students’ rights in relation to bullying and victimization on the basis of characteristics such as ethnicity or sexual orientation, and the law requires schools to implement policy and investigation processes. This legislation was preceded by the death by suicide of 13-year-old Seth Walsh who was harassed about sexual orientation and identity, and requires that policy adopted by educational agencies prohibit discrimination, harassment, intimidation, and bullying based on actual or perceived characteristics. Similarly, the death of a young woman, Brodie Panlock, following victimization by bullying in the workplace preceded the introduction of Brodie’s Law (<http://www.justice.vic.gov.au/home/safer+communities/crime+prevention/bullying+-+brodies+law>) in Victoria, Australia. This law pertains to serious bullying such as physical bullying, psychological bullying, verbal bullying, and cyberbullying and applies to workplaces, schools, sports clubs, and the Internet. Serious bullying may include behaviours that are intended (or could reasonably be expected) to lead to suicidal thoughts and thoughts or actions relating to self-harm. It is evident that whilst some

legislation places obligations on schools to implement best practice and appropriate policy, other legislation allows for prosecution of those who perpetrate bullying and aggression. There is a great debate as to whether criminalizing cyberbullying and aggression is the most effective way of coping with this undesirable and potentially harmful behaviour. Despite this, we should remember that civil society and ourselves, as citizens, have signed up for, and accepted, the principles of the UN Convention on the Rights of the Child - particularly the notion of an education free from harm and harassment.

Reviewing some of the approaches in an American context, Szoka and Thierer (2009) argue that when attempting to cope with cyberbullying, education is preferable to criminalization. They argue that attempts to introduce cyberbullying-specific law means that cyberbullying perpetration could carry much more severe repercussions than traditional bullying. In a case of traditional bullying, perpetrators may be provided with counselling, whereas if they conduct such aggressive behaviour online, they could face incarceration in a federal prison. Szoka and Thierer (2009) argue that those who create legislation could alternatively focus on supporting Internet safety education and awareness-raising strategies. They cite the “School and Family Education about the Internet (SAFE Internet) Act” (see <https://www.congress.gov/bill/111th-congress/senate-bill/1047/text>) which facilitates outputs such as: implementation of Internet safety education programmes; provision of training to teachers and other school staff; development of online-risk prevention initiatives for children; peer-driven Internet safety education; and parent education which can support guidance of children in terms of Internet and new media safety. They also highlight important issues when considering legislating for cyberbullying. For instance, the fact that the definition of cyberbullying (or peer-to-peer cyber aggression) is still evolving poses certain challenges, such as the possibility of creating a law that also targets other forms of cyber abuse, such as cyber harassment or cyberstalking – distinct but perhaps overlapping behaviours. It is also important to consider whether such legislation should only apply to minors. Szoka and Thierer (2009) also highlight the issue that criminalizing children for cyberbullying can stigmatize them for ill-judged behaviours of their childhood or youth. They suggest that this form of aggression should instead be dealt with by education, awareness-raising, and appropriate discipline and counselling procedures at school level. In other words, they recommend taking an “educate first” approach; an approach which may equip children and adolescents with skills and strengths that will serve them long after they have finished school. Furthermore, they raise the important point that, just as we teach children etiquette and manners for the physical world and we try to equip them with skills so as to navigate risk in the “real world,” we must do so in the cyber world. Until we can properly assess the impact of cyberbullying legislation, it is difficult to definitively state that such an approach is an inferior coping strategy. Certainly, it is important to enforce laws that are responsible and thoroughly considered.

Child pornography laws have exemplified exactly the types of challenges created by the black and white nature of legislation, with children sometimes being prosecuted for sharing intimate photos of their own bodies. Levick and Moon (2010) state that

Prosecuting sexting cases as child pornography is a gross misapplication of child pornography statutes by using them as a sword and not a shield to protect exploited child victims. Sending more youth into the juvenile delinquency system for behaviour that is consistent with normative adolescent development unnecessarily exposes youth to the

stigma and collateral consequences that flow from a delinquency adjudication, including possible sex offender registration (p. 1035).

It could be argued that prosecuting children for any type of cyber-crime is attempting to protect children with a sword rather than a shield.

CONCLUSION

Having reviewed the background theories that are important in the area of coping and cyberbullying/cyber aggression, this chapter sought to contextualise the current knowledge regarding the most efficacious ways for CYP and others (e.g., schools, families) to cope with such insidious behaviours. The “take home” message from this chapter is that, as we advance rapidly into the future, perhaps we should reach back to our past - and pause - for inspiration. Quite often in our research endeavour to help ameliorate social and educational concerns, we are afforded the chance by “the academy” to “stop and stand and stare”, and consider not just the empirical facts and theoretical suppositions, but also the anecdotal knowledge of our parents, grandparents, and forbearers. To what extent is the problem of coping with cyberbullying different from the trials and tribulations of our Cro Magnon ancestors, who perhaps had to chastise and teach their offspring regarding the potential negative effects of daubing “certain images” on the caves they inhabited. And so, with “your grandmother” in mind, along with the emerging empirical knowledge in the area, consider how we do our best for the CYP of today - and tomorrow. Whilst today will come and today will go, the coping issues of concern to this chapter will be quickly superseded by the concerns now emerging regarding racism, xenophobia, and online radicalization.

Chapter 146

CYBERBULLYING AND MENTAL HEALTH: INTERNET-BASED INTERVENTIONS FOR CHILDREN AND YOUNG PEOPLE

Nicole Gunther*, Francine Dehue and Viviane Thewissen

Faculty of Psychology and Educational Science,
Open University of the Netherlands, Netherlands

INTRODUCTION

This chapter addresses intervention efforts for youth to prevent and combat cyberbullying and its subsequent negative impact on mental health, with emphasis on the potential advantages of Internet-based interventions.

CYBERBULLYING: THE IMPACT ON MENTAL HEALTH

The word “cyberbullying” did not exist a decade ago (Notar, Padgett, & Roden, 2013). Hence, although traditional bullying is found to have negative consequences for the psychological, social, and physical health of both the bullies and victims involved (Bauman, Toomey, & Walker, 2013; Tokunaga, 2010), there is a delay in the clinical research community in recognizing cyberbullying experiences as an important risk factor for developing mental health problems (Foody, Samara, & Carlbring, 2015). However, studies on the negative impact of cyberbullying for bullies, victims, and bully/victims have emerged over the last decade. Most of these studies focused on the negative impact related to victimization and showed that the psychological and emotional consequences of cyberbullying represent the largest problem (Dredge, Gleeson, & de la Piedad Garcia, 2014; Jang, Song, & Kim, 2014). Due to its repetitive and pervasive nature, cyberbullying has detrimental short- and long-term effects on the mental health of the children and young people (CYP) victimized. Cross-sectional studies and a few

* Corresponding Author’s Email: Nicole.Gunther@ou.nl.

longitudinal studies have linked cyber victimization to stress, low self-esteem, anxiety, depression, and suicidal ideation (Bauman et al., 2013; Bonanno & Hymel, 2013; Campbell, Spears, Slee, Butler, & Kift, 2012; Cénat et al., 2014; Goebert, Else, Matsu, Chung-Do, & Chang, 2011; Helwig-Larsen, Schütt, & Larsen, 2012; Hinduja & Patchin, 2010; Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Lam & Li, 2013; Mitchell, Ybarra, & Finkelhor, 2007; Patchin & Hinduja, 2010; Reed, Cooper, Nugent, & Russell, 2016; Selkie, Kota, Chan, & Moreno, 2013; Wang, Nansel, & Iannotti, 2011). However, the few longitudinal studies available suggested that cyberbullying may be causally related to depression, though depressed CYP are also more vulnerable to cyberbullying (Gámez-Guadix, Orue, Smith, & Calvete, 2013), or indicated that some negative consequences were in fact predictors of cyber victimization (e.g., anxiety, low self-esteem) rather than consequences (van den Eijnden, Vermulst, van Rooij, Scholte, & van de Mheen, 2014; Yang et al., 2013).

Also, the experience of being a cyberbully has been linked to mental health outcomes. Cyberbullies often experience depression as well as cyber victims (Wang et al., 2011) and a study by Hinduja and Patchin (2010) found that cyberbullies report more suicidal ideation and more suicidal attempts than those not-involved in cyberbullying, but less than cyber victims. The worst impact on mental health has been related to being a bully/victim. Similar to traditional bully/victims, there is a consensus in the literature that the impact on mental health and need for help is heightened for this subgroup compared with non-involved CYP (Campbell et al., 2012; Låftman, Modin, & Östberg, 2013; Sourander, 2010) and other participant roles in cyberbullying (Chang et al., 2013; Gámez-Guadix et al., 2013), as they experience both problems related to victimization and those related to perpetration.

It is clear that a focus on prevention and intervention efforts is important to ensure the safety of CYP for whom technology is increasingly an academic and social necessity and way of living. Furthermore, research demonstrating correlations between cyberbullying and serious mental health problems underscore the clinical importance of assessing cyberbullying in CYP.

INTERVENTIONS TO PREVENT AND COMBAT CYBERBULLYING AND ITS NEGATIVE CONSEQUENCES

A limited number of interventions have been specifically designed for CYP involved in cyberbullying (Slonje, Smith, & Frisé, 2013), although parent-targeted messages do exist as well as school-based interventions such as “Medienhelden” (Wölfer et al., 2014), “ConRed” (Ortega-Ruiz, Del Rey, & Casas, 2012), “Let’s not fall in a trap” (Menesini, Nocentini, & Palladino, 2012), “Cyber friendly schools project” (Cross et al., 2016), and “Survivors” (Amse, 2014), containing, for example, lessons, videos, presentations, games, discussions, and workshops. However, most of these interventions are lacking scientific evidence due to, for example, a lack of inclusion of a follow-up measure and a failure to use random assignment at the classroom or school level. Moreover, only a few school-based programs are demonstrating positive effects (Della Cioppa, O’Neil, & Graig, 2015). Another disadvantage of these interventions is the involvement of parents and schools. Research has shown that youth victims of cyberbullying are reluctant to report experiencing cyberbullying to their parents and are even less likely to disclose cyberbullying abuse to teachers, school personnel, or physicians (Li, 2010; Slonje & Smith, 2008; Smith et al., 2008). For example, a study by Dehue, Bolman, and

Völlink (2008) showed that 11% of the parents reported that their child had been cyberbullied, compared to almost 23% of their children. Moreover, the study suggested that only 20% of the victims of cyberbullying talked about their experiences, from which 3% with their parents and only 1% with their teachers. The reasons to keep cyberbullying incidents to themselves include the need to manage or deal with cyberbullying individually, feelings of shame, and fear of being restricted in the use of electronics (Juvonen & Gross, 2008), and hence, isolation from peers (Kraft & Wang, 2009). Furthermore, today's CYP spend significant amounts of time online (Lenhart, Purcell, Smith, & Zickuhr, 2010), prefer to get anonymous help (Webb, Burns, & Collin, 2008), and report a need for information and help through the Internet (Havas, de Nooijer, Crutzen, & Feron, 2011).

As a result, parent-targeted intervention messages are often insufficient due to CYP's reluctance to disclose experiencing cyberbullying to their parents (Ybarra, Diener-West, & Leaf, 2007). School-based interventions are insufficient for the same reason, but they are also not equipped to provide individualised psychological support to victims as they are normally focused on children and adolescents only in the form of a whole school approach and/or standard care packages (Foody et al., 2015). Therefore, the Internet becomes the next logical method for reaching children and adolescents struggling with the consequences of a cyberbullying incident.

INTERNET-BASED MENTAL HEALTH INTERVENTIONS

The Internet is increasingly becoming an integral part of the daily lives of people of all ages, and particularly of young people. More than three-quarters of European households (83%) had access to the Internet in 2015 and 94% of those aged 16-24 were regular Internet users in that year (Eurostat, 2013, Eurostat, 2015). To communicate with each other, CYP frequently make use of electronic communication tools on the Internet, such as chatrooms and social networking sites, and applications on their smartphones (Lenhart et al., 2010; Patchin & Hinduja, 2010). As Kowalski and colleagues state, the Internet is a critical tool for their social life (Kowalski, Limber, & Agatston, 2008). The health care sector uses this trend and develops online prevention, treatment, and support systems, collectively referred to as e-mental health. E-mental health has been defined as "... the use of information and communications technology (ICT) to support and/or improve mental health and mental health care" (Blankers, Donker, & Riper, 2013, p. 13). In this chapter, e-mental health refers to Internet-based interventions focusing directly on the mental well-being of the consumer.

Recently, Internet-based mental health interventions are gaining momentum (Lindfors & Andersson, 2016; Thewissen & Gunther, 2015). In the Netherlands for example, two out of three Dutch mental health care institutions apply e-mental health in their care provision and in communication with patients (such as e-consultations, e-appointments, and e-intakes). The number of people receiving Internet-based help for depression or eating disorders has tripled in a period of three years (GGZ-Nederland, 2013). The technological developments of Internet-based mental health interventions offer some benefits over traditional face-to-face interventions for both client and health care professional. For example, the low-threshold accessibility of the Internet makes it suitable for offering and receiving help for psychological problems, and clients who are treated on the Internet can avoid the stigma incurred by seeing a therapist (Gega,

Marks, & Mataix-Cols, 2004). In addition, CYP find it easier to communicate about thoughts and feelings online than face-to-face (Livingstone & Bober, 2004). Other benefits of these interventions that are mentioned in literature are “obtaining help at any time and place”, “working at one’s own pace,” and “reviewing the material as often as desired” (Spek et al., 2007). Also, because of the long waiting lists and, hence, treatment delays of traditional face-to-face interventions, the greater accessibility of Internet-based interventions make them an attractive treatment alternative. Given the need for early intervention in mental health disorders, long delays in receiving treatment could have devastating effects.

Based on the level of therapist involvement, Internet-based mental health interventions can be divided into self-guided interventions (information and advice, self-tests, and unsupervised self-help programs; no assistance; mainly prevention), guided self-help (minimal therapist contact by email, chat, telephone, or face-to-face sessions), and online psychotherapy (Ruwaard, 2013). However, the differences in effectivity between guided self-help and online psychotherapy cannot easily be determined, because in research the terms “guided self-help” and “online psychotherapy” are often used interchangeably (for example Johansson, Frederick, & Andersson, 2013).

One of the core factors discussed in the context of effectiveness of Internet-based mental health interventions, is guidance as part of these interventions. Literature so far has suggested that users benefit more from Internet-based mental health interventions when guidance is provided. For example, it was shown from a recent systematic review and meta-analysis (Baumeister, Reichler, Munzinger, & Lin, 2014) that guided Internet-based mental health interventions are significantly more effective than unguided Internet-based mental health interventions. Evidence further suggests that the qualification level of the therapist providing guidance might be of minor importance. Internet-based mental health interventions have proven their added value in prevention and early interventions for mental health problems such as depression, addiction, suicide, and eating disorders (GGZ-Nederland, 2013). Looking into Internet-based treatment interventions (guided self-help and online psychotherapy) usually an approach based on cognitive behavioural therapy (CBT) is at the heart of these interventions. CBT is characterized by clear-cut therapeutic procedures which are relatively easy to translate into a format suitable for delivery over the Internet (Ruwaard, 2013). In addition, CBT has been found to be an effective treatment for a wide range of mental health problems in children and adolescents, including anxiety disorders and depression (James, James, Cowdrey, Soler, & Choke, 2013; McDermott et al., 2010). A recent systematic review showed that Internet-based CBT (guided self-help) is associated with significant reductions of symptoms of depression, panic disorder, and social anxiety disorder in adults (Hedman, Ljótsson, & Lindefors, 2012). Also, meta-analyses showed that Internet-based CBT and face-to-face CBT were equally effective in the above mentioned disorders and population (Andersson, Cuijpers, Carlbring, Riper, & Hedman, 2014; Cuijpers, Donker, van Straten, Li, & Andersson, 2010). Although Internet-based treatment interventions are promising in reducing symptoms related to depression, panic disorder, and social anxiety disorder in adults, more research in this context is needed.

In recent years, there is growing attention for Internet-based treatment interventions for children and adolescents with mental health problems (Spence, March, Vigerland, & Serlachius, 2016). But how effective are these interventions? To give an answer to this question, several randomized clinical trials have been conducted to investigate the effectiveness of Internet-based treatment interventions for children and adolescents with mental health

problems. These trials focused exclusively on anxiety symptoms and assessed Internet-based cognitive behavioural therapy. They demonstrated positive effects for the Internet-based intervention relative to the control group and these interventions were equally effective as the face-to-face intervention group (Khanna & Kendall, 2010; March, Spence, & Donovan, 2009; Spence et al., 2011; Spence, Holmes, March, & Lipp, 2006). There were also some trials reporting positive results on the effectiveness of Internet-based CBT for youth depression, but these interventions focus on prevention, rather than treatment (for example Stasiak, Hatcher, Frampton, & Merry, 2014). Hence, there is growing evidence for the effectiveness of Internet-based treatment interventions based on CBT for reducing the level of anxiety symptoms, but more research is needed to strengthen the evidence base for prevention and treatment programs that are delivered via the Internet, particularly for depression and other disorders in children and adolescents, such as eating disorders. In the next paragraph, existing Internet-based prevention and treatment interventions for cyberbullied CYP and their effectiveness are outlined.

INTERNET-BASED INTERVENTIONS FOR CYBERBULLIED CYP WITH MENTAL HEALTH PROBLEMS

As mentioned above, it is common to find that adolescents have been cyberbullied for a long time before reporting it to adults, such as their parents, teachers, or health professionals (Dehue et al., 2008; Juvonen & Gross, 2008; Li, 2010), even though cyberbullying can be very emotionally distressing. Many of these cyberbullied adolescents with mental health problems do not seek help from professional services, although effective treatment is needed. The most significant barriers to seeking help for mental health problems in this age group are perceived stigma and embarrassment, an inability to access services because of extended waiting lists, geographical dispersion, costs of services, and, in the case of cyberbullying, poor awareness about how this impacts their psychological functioning (Gulliver, Griffiths, & Christensen, 2010; Rickwood, Deane, Wilson, & Ciarrochi, 2005; Zalpuri, 2015). Another complication associated with cyberbullying is that *when* they come to health professionals, they often present their problems to these health professionals as general symptoms of depression, anxiety, and refusal to attend to school. Therefore, the trigger for these mental health problems may be missed, unless paediatricians and child psychiatrists routinely screen specifically for cyberbullying (Zalpuri, 2015). Many adolescents will never report that they are being cyberbullied, unless asked directly (Li, 2010). Therefore, according to Zalpuri (2015) a thorough psychiatric evaluation of CYP must also include questions about bullying and cyberbullying.

Hence, there is an urgent need for Internet-based treatment interventions for CYP with mental health problems as a result of involvement in cyberbullying. Youths appear to engage regularly in online activities, regardless of the risk of cyberbullying, so developing an Internet-based treatment that is readily available to them is strongly encouraged (Reed et al., 2016). The Internet is now widely used to provide Internet safety tips, cyberbullying prevention tips, and tips for managing cyberbullying for parents, teachers, and young people. In the context of prevention and early intervention of cyberbullying, a qualitative study by Ahlfors (2010) analysed the general information and themes available on 17 websites (written in English and

in the public domain) dedicated strictly to cyberbullying prevention and intervention. Of the 17 cyberbullying websites, the most frequently addressed population are parents/caregivers and not the populations most in need of Internet-based cyberbullying interventions, the cyber victims and cyberbullies. In fact, none of the reviewed websites were specifically designed for cyberbullies. Most of the reviewed websites are used as a source of information for Internet safety tips and cyberbullying prevention tips. Only five of the reviewed websites can be categorised as intervention websites and give specific directions to parents, teachers, or cyberbullied children and cyberbully witnesses to manage cyberbullying. Only one of these five websites pays (minor) attention to the negative outcomes of being bullied by introducing a screening instrument for depression. Also in the Netherlands, many cyberbullying prevention and intervention websites have been developed in recent years to address the growing problem of cyberbullying (for example <http://www.pestweb.nl> and <http://www.internethulpverlening.nl>).

Apart from the fact that almost none of the available websites contain Internet-based treatment interventions, a main problem is that many of these materials and programs do not have a theoretical base, and that the effectiveness of these websites in decreasing incidences of cyberbullying and its consequences has not yet been investigated (Ahlfors, 2010; Völlink, Dehue, Mc Guckin, & Jacobs, 2016). A starting point to investigate the effectiveness of these cyberbullying websites should be to determine how many people access the websites as well as to determine whether the information was of help or not (Ahlfors, 2010).

While cyberspace is the perfect location to offer interventions for individuals experiencing negative consequences of cyberbullying, as far as we know, no evidence-based Internet-based mental health interventions are developed addressing directly cyberbullied CYP with mental health problems. Although the web-based online intervention *Pestkoppenstoppen.nl* (Stop Online Bullies) is a promising approach to the problem, with a theoretical base and aiming to teach victims effective ways of dealing with anxiety and depression associated with cyber victimization without the interference of adults (Jacobs, Völlink, Dehue, & Lechner, 2014), empirical evidence is lacking and at present no randomised control trial (RCT) or effect sizes are available to demonstrate its effectiveness.

A worthwhile action would be to look at current Internet-based mental health interventions for CYP, such as online CBT, showing positive outcomes in terms of reduction in symptoms associated with a broad range of psychological disorders, and incorporate some of their modules into an online programme for cyberbullied CYP with mental health problems. An alternative is to incorporate a cyberbullying module into current Internet-based mental health interventions for CYP with, for example, depression. However, we are a long way from knowing what the ideal format is because Internet-based mental health interventions for CYP are developed to a much lesser extent than those for adults and do not focus on the whole range of mental health problems. Furthermore, the number of effectiveness studies in CYP is limited and studies are mainly directed at anxiety disorders. Hence, more studies are needed on CYP-focused Internet-based programs as a whole that include, within one design, a control group, an intervention group that has undergone a proven effective face-to-face therapy, and an online intervention-based therapy, with special attention for mental health problems associated with cyberbullying. Also, more effectiveness studies on Internet-based mental health interventions for CYP as well as on cyberbullying interventions have to be conducted with a specific focus on the “critical ingredients” or the key processes that lead to reduction in mental health problems in general, but also to reduce mental health problems associated with cyberbullying.

Furthermore, effectiveness studies have to give an answer to questions such as “for whom does CBT/cyberbullying interventions work and under what context?” and “what is the best quantity and quality of therapist support or guidance?”

Despite these reservations, the literature to date is encouraging and suggests that Internet-based mental health interventions for children and adolescents are promising and rapidly expanding. It is not likely that Internet-based mental health interventions will completely replace traditional face-to-face therapies. In fact, blended care, a combination of online and traditional face-to-face contact, is increasingly being applied in mental health care (Thewissen & Gunther, 2015). In this context, a promising treatment for cyberbullied CYP with mental health problems, such as depression, would be blending online cyberbullying modules into face-to-face sessions in order to obtain the optimal benefits from the advantages of these two treatment modalities.

CONCLUSION

Internet-based interventions might be an effective way to overcome treatment barriers of traditional face-to-face interventions for cyberbullied CYP with mental health problems. However, research to date shows that no evidence-based Internet-based mental health interventions are developed addressing directly cyberbullied CYP with mental health problems. Also the number of studies on the effectiveness of Internet-based mental health interventions for CYP is limited. More methodologically sound research on the effectiveness of Internet-based mental health interventions and cyberbullying interventions should be considered a crucial step forward in the development of Internet-based interventions for cyberbullied CYP with mental health problems. Future research needs to investigate the process at work in these interventions, in addition to how to include a cyberbullying module as part of face-to-face sessions.

Chapter 147

THE AUSTRALIAN PERSPECTIVE: EFFORTS TO COUNTER CYBERBULLYING

Marilyn Campbell*

Queensland University of Technology, Australia

INTRODUCTION

Australian young people have easy access to technology with 89% of 14-17 year-olds using the Internet and 89% accessing a mobile phone with 69% of this group owning or using a Smartphone (one with Internet access, television, and multi-media) (Australian Communications and Media Authority: ACMA, 2014). Additionally, 70% of 12-14 year-olds use social networking sites (Australian Bureau of Statistics, 2012). Australian research has shown that although most of these young people use this technology appropriately and gain advantages in access to information and social communication, there are also those who use it to cyberbully others.

DEFINITION

Defining what we are talking about is fundamental to all research and to prevention and intervention of cyberbullying. Since Bill Belsey coined the term cyberbullying in 2004 it has eclipsed other words such as e-bullying, electronic bullying, or technological bullying. Without a consensual definition of cyberbullying however, measurement difficulties arise which impacts upon the development of prevention and intervention strategies. There have been many Australian contributions to the continuing debate on the definition of cyberbullying.

The arguments regarding the most appropriate term are usually conceptualised first by a broad question of “is cyberbullying a form of bullying”; or “is it a different subset of aggression from traditional or face-to-face bullying” in which case the word bullying needs to be removed.

* Corresponding Author’s Email: ma.campbell@qut.edu.au.

Bullying is characterised by what most researchers agree are three fundamental pillars of bullying: intention, repetition, and power imbalance (Olweus, 1993).

One of the first Australian papers to consider the theoretical and conceptual similarities of cyberbullying and face-to-face bullying (or traditional bullying) was by Dooley, Pyżalski, and Cross in 2009. In this paper, it was argued that Olweus' (1993) definition of bullying, which differentiates it from aggression, is the repetitive nature and the imbalance of power involved in bullying, and thus cyberbullying needs to evidence these factors if it is to be considered bullying. It was argued that even though repetition in cyberbullying can be different from traditional bullying, in that for instance, a single act of a cyberbully may become viral and therefore "repeated" it is a factor in cyberbullying. The factor of imbalance of power between the perpetrator and the victim is considered fundamental to distinguishing aggression and bullying. However, Belsey (2004), in common with some North American researchers (e.g., Justin Patchin, Michele Ybarra), did not include this factor in his definition of cyberbullying as "... the use of information and communication technologies to support deliberate, repeated and hostile behavior by an individual or group that is intended to harm others". This could be interpreted as fighting among equals and continues to be a contentious point between North American scholars and others.

Another Australian, (Langos, 2012) has also contributed to this debate on the definition of cyberbullying following the same arguments on the two fundamental propositions of repetition and imbalance of power, and adding an interesting classification of the subjective nature of intention, resolving whether it is a perpetrator's intent or the victim's perception of the act that should be considered. Following a legal tradition she suggested that "... intention is best determined based on how a reasonable person would perceive the perpetrator's conduct" (p. 288).

Recently, the Australian Research Alliance for Children & Youth (ARACY) proposed a definition of school-based bullying as:

... a systematic abuse of power in a relationship formed at school characterised by: 1. Aggressive acts directed (by one or more individuals) towards victims that a reasonable person would avoid; 2. Acts which usually occur repeatedly over a period of time; and 3. Acts in which there is an actual or perceived power imbalance between perpetrators and victims, with victims often being unable to defend themselves effectively from perpetrators (Hemphill, Heerde, & Gomo, 2014, p. 3).

Independently, at the same time, the United States Center for Disease Control also issued a statement that cyberbullying or electronic bullying can be identified using the general definition of bullying which:

... is any unwanted aggressive behavior(s) by another youth or group of youths who are not siblings or current dating partners that involves an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated (Gladden, Vivolvo-Kantor, Hamburger, & Lumpkin, 2014, p. 7).

It will be interesting to note if this definition, agreed on by eminent bullying researchers in Australia and North America will be taken up world-wide or some other definition is reached so that the field can progress in measurement and prevention efforts.

PREVALENCE

The first published study in Australia on cyberbullying reported that in a small sample of 120 students in Year 8 (13-year-olds), 14% claimed to have been cyberbullied while 7% reported they had cyberbullied another student during that year (Campbell, 2005). One large national study of 7,500 8-14 year-olds reported that 7% had been cyberbullied frequently (every few weeks in the last 3 months) with 3.5% reporting frequently bullying others (Cross et al., 2009). In 2011, Campbell and colleagues found in a national sample of over 3,000 students that 14% were cyberbullied and 7.6% cyberbullied others (Campbell, Spears, Slee, Kift, & Butler, 2011). Other Australian studies have found cyberbullying victimisation rates of 11.5% (Sakellariou, Carroll, & Houghton, 2012) and 13.4% (Hemphill, Tollit, & Kotevski, 2012).

It is of course difficult to make accurate comparisons between these studies to ascertain what trends there are in cyberbullying in Australia because of the different age groups and cut points for frequency, national and state samples, as well as studies including both or one gender. However, in 2014 in reviewing Australian cyberbullying victimisation prevalence studies, it was estimated that about 20% of young people aged between 8-17 years old had been victimised in this way (Katz et al., 2014). This is similar to international studies showing that students between the ages of 10-15 years old were cyber victimised the most (Genta et al., 2012).

Cyberbullying in Australia is not confined, however, to young people. It has been documented in a sample of 91 TAFE (Technical and Further Education) students in Victoria that 9% were cyberbullied (Reeckman & Cannard, 2009). Two studies of university students in Australia also reported cyberbullying; one with 528 students found 11.6% were victims of cyberbullying in the preceding 12 months (Wensley & Campbell, 2012), and one with 282 students found 14.5% had been victimised by these means (Wozencroft, Campbell, Orel, Kimpton, & Leong, 2015). Cyberbullying has also been shown to occur in the Australian workforce, with 10.7% of a sample of 103 workers belonging to the Australian Manufacturing Workers' Union being cyberbullied (Privitera & Campbell, 2009).

RESEARCH

Australian research has also contributed to our understanding of: (a) the consequences of cyberbullying on both the perpetrator and the student who is victimised; (b) the motives of those who cyberbully; and (c) the actions of bystanders to cyberbullying. This is all vital information in our efforts to counter cyberbullying.

Consequences

It has been shown that Australian students who were cyber victimised reported more social difficulties and higher levels of depression and anxiety than those students who were victims of traditional bullying (Campbell et al., 2012). While these are serious sequelae for students who are victims of cyberbullying, those students who are perpetrators also reported more social difficulties and obtained higher scores on stress, depression, and anxiety scales than students not involved in bullying (Campbell, Slee, Spears, Butler, & Kift, 2013). Additionally, in a

longitudinal study of 650 Australian high school students it was found that cyber victimisation was linked to depressive symptoms one year later, whilst cyber perpetration was linked with theft. Furthermore, if the student was involved in both cyberbullying perpetration and was also a victim, they were more likely to be suspended from school and involved in binge drinking one year later (Hemphill, Kotevski, & Heerde, 2015).

It has also been shown that students who were cyber victimised were less likely to seek help than those who were victimised by more traditional means (Dooley, Grading, Strohmeier, Cross, & Spiel, 2010). Cyberbullying victims in Australia also appear unwilling to seek help from online services, including self-help apps and websites (Spears, Taddeo, Daly, Stretton, & Karklins, 2015).

Motives

The motives that propel students to bully in traditional ways have been well documented: the need to belong (Owens, Shute, & Slee, 2000), influence from families (Rigby, 1994), and victim provocation (Rose & Rudolph, 2006). When Australian adolescents were asked why young people cyberbullied, the reasons were to "... get attention from others, make themselves feel better and to get their own way" (Wilton & Campbell, 2011, p. 107). Those students who engaged in cyberbullying said it was good to be able to be someone else. In a follow-up study, teachers and parents as well as students were asked what motivated students to cyberbully (Compton, Campbell, & Mergler, 2014). Interestingly all three groups perceived a different main motivation for young people to cyberbully. Teachers perceived the main motivation was that it was easy for students to cyberbully. Parents thought that being able to be anonymous was the reason that young people bullied, while students reported that they thought the main motivation to cyberbully was to be able to avoid retaliation from victims or punishments from teachers and parents.

Bystanders

We know that bystanders to traditional bullying can influence this behaviour as their actions can either escalate or stop this behaviour by passively watching, joining in, or intervening to stop the bullying (Rigby & Johnson, 2006; Trach, Hymel, Waterhouse, & Neale, 2010). Less is known about bystanders to cyberbullying. Two Australian studies have explored this topic. Duncanson et al. (2015) found in a study of over 3,000 students that bystanders to cyberbullying responded differently to bystanders to traditional bullying. Bystanders to traditional bullying more frequently endorsed telling parents, friends, and adults whereas bystanders to cyberbullying were more likely to help the person being cyberbullied, stand up to the person cyberbullying, or get back at the bully later. It was hypothesised that this difference could be because of the lower risk of harm to the bystander in taking action in cyberbullying. Following on from this study another project explored whether bystanders to traditional and cyberbullying used online methods or face-to-face encounters or both, when taking action to report the bullying, stop the bullying, or support the victim (Sheppard & Campbell, 2015). It was found that most of the young people surveyed would take action as a bystander to either traditional or cyberbullying in person, when they reported the bullying or

when they were supporting the student who was victimised. However, when it came to intervening directly with the student who was bullying, bystanders told traditional bullies to stop face-to-face and cyberbullies to stop by online methods.

PREVENTION AND INTERVENTION EFFORTS IN AUSTRALIA

In this section the influence of the media is examined in reporting on cyberbullying in Australia. This is followed by a description of the legal arguments fuelled by the media about how to reduce cyberbullying. The place of anti-bullying policies in schools is then discussed. A description of the resources provided by the Australian government and the many non-government agencies follows. Finally, current research projects which are investigating prevention and intervention efforts are described.

Media in Australia

Mass media has a significant influence on society (Macnamara, 2005) as explained by the agenda setting theory (McCombs & Shaw, 1972) which postulates that the media determines what people think about. Issues which are reported frequently in the media are issues which will be high on the public's agenda and consequently important to policymakers. Online risks to young people, such as cyberbullying, are relatively high on the media agenda in Australia. In a content analysis study, it was found that there was sustained media attention in the 10 year period from 2001 to 2011 on articles about bullying and cyberbullying (Kimber & Campbell, 2015). The articles were framed in different ways by the two newspapers, one of which would be considered in terms of popular journalism and the other in terms of quality journalism. The articles ranged from where cyberbullying was the main issue in the article to those about e-safety concerns in general. Similar to Vandebosch, Simulioniene, Marczak, Vermeulen, and Bonetti (2013), it was found that the "quality" newspaper was found to publish less articles on cyberbullying and had a more neutral and reassuring tone than the popular newspaper which portrayed cyberbullying in a light that could give rise to moral panic. These are examples not only of the media setting the agenda for the public to think about but also of the role of framing of such agendas, that is, reconstructing the story from a certain angle (Scheufele, 2000).

In the case of cyberbullying, most media reports on young people and the Internet take a negative news perspective. The way media frame an issue can have an impact on how people think about it and can determine their knowledge, attitudes, and behaviour with regard to the problem (De Vreese, 2005). If an issue is framed disproportionately and without proper evidence as a problem it is called a moral panic (Burger & Koetsenruijter, 2008).

It would seem in Australia that there are some indications that the media is portraying cyberbullying as a moral panic, with negative overtones (Kimber & Campbell, 2015), which has not been the case for traditional bullying. The consequences of cyberbullying and the seriousness of this issue have been brought to the attention of the public which has been useful in alerting society to what is happening. However, confronting stories of the suicide of adolescents and adults both overseas and in Australia who have been the target of cyberbullying (Lannen, 2009; Wise, 2009) is not helpful as most of these incidents involved mental health

problems as well as cyberbullying. This is consistent with studies that have found that there is a tendency in the media to link suicide and cyberbullying (Thom et al., 2011).

Media attention usually results in calls from the public for solutions to the problem and thus there are many calls for “something to be done” about cyberbullying in the media. The reaction to this media hype/attention in Australia has had the community and politicians calling for a law against cyberbullying and to have the police involved in instances of cyberbullying although there is no law against cyberbullying in Australia (Langos, 2014) to enable police to act.

Legal Responses

One of the responses to cyberbullying in young people in Australia is the community debate regarding the law and cyberbullying. Australia at present does not have a specific law against cyberbullying (Butler, Kift, & Campbell, 2009), which means that these behaviours are not legally defined and cannot be prosecuted (Langos, 2013). However, there are criminal offences that can be enforced against these behaviours, such as misuse of telecommunications, indecent filming, stalking, and criminal defamation (see Department of Communications Discussion Paper, Appendix B, Current Offences in the Criminal Code Act, 2014). Cases of traditional bullying in schools have led to civil claims for compensation or prosecution in the criminal courts in Australia (Campbell, Cross, Spears, & Slee, 2010). However, there has yet to be a reported case seeking civil compensation for cyberbullying and only one criminal prosecution arising from a case of a young adult involving threatening SMS messages (Milovanovic, 2010).

It is interesting to note that the general public in Australia has not called for changing laws to prevent or punish students who bully face-to-face. There could be several reasons for this. The first is that adults have not grown up with technology and often feel they do not understand this world which young people inhabit. As youngsters themselves they have had no experience of cyberbullying and so feel some degree of panic when confronted with this phenomenon (Campbell & Zavrsnik, 2013). Second, as previously argued, the constant media attention that cyberbullying attracts and the links that the media draws between cyberbullying and suicide could be reasons why adults are calling for specific laws to punish young people who cyberbully. The coining of the word “bullicide” illustrates the prominence given to students with mental health problems who are cyberbullied and then take their own life (Hinduja & Patchin, 2010).

The community mainly sees that the law exists to punish people, however, considering the ages of young people who cyberbully, this is a potential problem as in Australia children below the age of 10 are not deemed capable of criminal intent and it is up to the courts to decide if the child is capable between the ages of 10 and 14 (Butler, Kift, Campbell, Slee, & Spears, 2011). Additionally, the law is seen as a deterrent as it is thought that the fear of punishment will deter young people from cyberbullying. However, due to the impulsiveness of young people and the fact that they do not believe they can be caught cyberbullying, a law for this purpose might not work.

The convening of the Bullying, Young People and the Law symposium held in Melbourne, Australia, in 2013, was one effort to examine ways of reducing cyberbullying by legal solutions. The symposium was attended by pre-eminent legal, law enforcement, and educational experts

from Australia and New Zealand. Its recommendations were to introduce an appropriate legal framework to address bullying and cyberbullying in Australia, establish a national digital communication tribunal, and to continue to provide education about cyberbullying. Public consultation was also called for by the Federal Department of Communication in 2014 to explore options under Commonwealth legislation to deal with cyberbullying.

An interesting study garnered the views of Australian education employees' perceptions of cyberbullying and the law (Young et al., 2015). All the interviewees held senior authoritative positions in either education or the law or both. Overall, participants were divided in their support for the introduction of a specific law for cyberbullying, mirroring both the wider community and the scholarly world's views (Katz et al., 2014). Participants identified many sanctions which they thought would be appropriate for children and adolescents who persist in cyberbullying: such as mediation, victim impact statements, family conferences, bonds, cautions, and taking a juvenile justice team approach (Young et al., 2015).

In 2015 the Federal government enacted the "Enhancing Online Safety Act 201". This statute established a Children's e-Safety Commissioner and provides for a complaints system for Australian children who are cyberbullied. Removal of cyberbullying material from large social media services, such as Facebook and YouTube, will be at the service providers' discretion, using their own procedures to handle complaints of harassing materials posted on their services. Other smaller social media services are subject to direct regulation. The Commissioner on receiving a complaint of cyberbullying material may give a binding direction to have the material removed within 48 hours or the service could be subject to a civil penalty. The statute has no effect on existing laws about cyberbullying and still leaves the question of enacting a specific cyberbullying law open.

Policy

Even though cyberbullying occurs mainly outside of school property and school hours (Smith et al., 2008) the consequences often interrupt school life and impact on student learning (Bhat, 2008), so many believe efforts to combat cyberbullying to be a school responsibility. Thus, another strategy used to counter cyberbullying in Australia is the school anti-bullying policy. Having an anti-bullying policy that incorporates proactive policies, plans, and practices that reach beyond the school is an important strategy suggested both nationally and internationally to assist schools to prevent and intervene in instances of cyberbullying (Cross, Monks, Campbell, Spears, & Slee, 2011).

The Australian government was one of the first to provide leadership internationally in this area by providing schools with a set of guiding principles regarding the provision of a safe and supportive school environment called the National Safe Schools Framework (NSSF) (MCEERYA, 2003). This framework was developed to assist schools to both reduce bullying behaviour while improving the social and emotional health of the children in their school (Cross et al., 2011). The framework was first developed in 2003, revised in 2010, and updated in 2013. It sets out a vision and a set of principles for Australian schools taking a whole school approach aiming to promote student well-being by creating school environments in which members of the school community both feel and are safe from harassment, aggression, violence, and bullying. The policy was evaluated by Cross and colleagues (2011) four years after its implementation. While a small decline in self-reported bullying rates was observed from 1999

to 2007, it was concluded that the NSSF required greater implementation support and Australian teachers required further training.

A study by Butler et al. (2011), examined the anti-bullying policies of a small sample of Australian schools to gauge the extent of their readiness to respond to cyberbullying with regards to the potential liability they may face. The policy responses of nine schools were analysed to obtain a sense of how these schools were addressing cyberbullying according to the expectations of the law. Many of the schools' policies were found wanting in terms of inclusive definitions for cyberbullying, procedures to report cyberbullying, and processes by which complaints would be handled. Potential sanctions were often not included and policies were not seen to be sufficiently disseminated throughout the school community.

In trying to ascertain why these policies were poorly written, another study was conducted seeking the views of Australian education authorities' views on school policies concerning cyberbullying (Chalmers et al., 2015). In the Australian school system there are different education sectors in each state and territory, which provide schools in their jurisdiction with guidelines or templates for developing anti-bullying policies. Thus, there are different documents provided by each state which are supposed to adhere to the set of guiding principles of the NSSF. Therefore, the views of 10 key stakeholders in three states from Education Departments were sought in relation to their anti-bullying policies. Surprisingly, over half of the stakeholders did not mention the imbalance of power in their definitions of bullying for state education policies. The participants were divided in their opinions whether cyberbullying required a totally new anti-bullying policy, but most of them were advising their schools to have a 24-hour, seven day a week policy, to enable schools to officially deal with incidents between students that occur outside of school grounds and hours. This has not been the case for policies on traditional bullying in the past.

TEACHER TRAINING

Another initiative for countering cyberbullying in schools is the provision of resources for teacher training institutions. Teachers are often responsible for delivering anti-bullying programs in their classrooms and so the national project of Response Ability, which is an initiative of the Australian Government's Department of Health implemented by the Hunter INSTITUTE of Mental Health in partnership with tertiary educators throughout Australia (<http://responseability.org>) supports the pre-service training of school teachers. The project has many free, multi-media teacher resources on bullying and cyberbullying. It also provides additional information on its website and at conference presentations as well as support to tertiary educators to assist them to integrate mental health into their teaching.

Many studies have shown that pre-service teachers believe bullying is an important issue but express low levels of confidence to deal with it (Craig, Bell, & Leschied, 2011; Ryan & Kariuki, 2011). However, the present cohort of pre-service teachers has grown up with the National Safe Schools Framework as well as being part of the always-on generation. It was found in a recent study that most of the 717 pre-service teachers from three different states in Australia, in three different universities, were able to correctly identify cyberbullying situations from banter, conflict, and aggression. They also felt informed and capable of addressing bullying (Spears, Campbell, Tangen, Slee, & Cross, 2015).

ADVICE AND RESOURCES

The Australian Federal government has been very active in its efforts to counter cyberbullying among youth. There is also a government initiative of the Safe and Supportive School Communities, a national collaboration in which all States and territories have representatives. This project is under the auspices of the State Ministers of Education with a major outcome of the project being the website *Bullying. No Way!*

A government agency called the Australian Communication and Media Authority (ACMA) provides the Cybersmart program, a national cyber-safety education program. All the resources are provided free on their website (<http://www.acma.gov.au/Home/Citizen/Stay%20protected/My%20online%20world/Staying%20safe%20online>). The government along with the Principals Australia Institute and *beyondblue* provide a framework for secondary schools to promote mental health, providing training for schools and resources on their website (<http://www.mindmatters.edu.au/about-mindmatters/what-is-mindmatters>). A similar framework is available for primary schools called Kids Matter (<http://www.kidsmatter.edu.au/primary/about-kidsmatter-primary>). Both frameworks include resources on cyberbullying. Police in Australia also offer the Internet Safety program ThinkUKnow to parents and teachers (<http://www.thinkuknow.org.au/>).

Non-Government Agencies

Non-government agencies are also involved in countering cyberbullying. In addition to programs and resources, there are two main organisations which provide help for young people in the form of telephone or online counselling. Kids Help Line is an initiative of Boys Town and offers a free, private, and confidential telephone and online counselling services for young people between five and 25 years of age (<http://www.kidshelp.com.au/>). Also, Reach Out run by the Inspire Foundation (<http://au.reachout.com/get-involved/about-reachout>) offers online mental health services.

The Alannah and Madeline Foundation was set up by Walter Mikac after his wife and two children Alannah and Madeline were among 35 people shot dead at Port Phillip in Tasmania in 1996. The aim of the foundation is to prevent and intervene in all forms of violence against children. To this end one of their initiatives was the formation of the National Centre Against Bullying (NCAB). This Centre comprises expert researchers in bullying, practitioners, and policy makers. The Centre works closely with school communities, government, and industry. It is the peak body for anti-bullying messages in Australia and one of its main functions is to hold a biennial conference to disseminate the latest research on bullying. The Foundation also founded the e-Smart program in 2013. This program, for use in schools, has been designed to reduce the incidence and harm associated with cyberbullying.

The Alannah and Madeline Foundation has also run, in conjunction with a major national bank, a community service announcement across TV, press, radio, digital, outdoor, and cinema, highlighting the role of the bystander in bullying on the premise of “words are more powerful than you think – say something... find a voice for someone who can’t find theirs and help prevent bullying”.

While all these initiatives are useful, none is actually evidence-based and we have no way of knowing about the uptake of the resources. As these resources have not been empirically tested, it is vital for researchers in Australia to collaborate to build a research base on reducing cyberbullying. To respond to this need Professors Donna Cross, Phillip Slee, and Marilyn Campbell together with Dr Barbara Spears formed the Australian Universities' Anti-bullying Research Alliance (AUARA). This brought together university-based research teams from the University of Western Australia, Flinders University, Queensland University of Technology, and University of South Australia. AUARA has made submissions to the Federal Government on cyberbullying such as the Joint Select Committee on cyber-safety in 2011 (http://www.ap h.gov.au/Parliamentary_Business/Committees/House_of_representatives_Committees?url=js cc/index.htm) and have made significant international links with organisations concerned with the issue of cyberbullying including Canadian PREVNET; the International Observatory on Violence, and the Cyberbullying Action Network. AUARA established the Australia-India research collaboration in 2013 and worked with the European (COST) Action 1S0801 from 2008-2012. We hosted a four-day Training School in Melbourne, Australia for this action which is the first time a training school had been held outside of Europe. Led by Professor Donna Cross when she was at Edith Cowan University, AUARA was also funded for a Collaborative Research Network to build research capacity and produce evidence-based outcomes to reduce harm from cyberbullying from 2011-2014. Some of these major research projects are outlined below.

RESEARCH PROJECTS

Cyber Friendly Schools

Donna Cross and her colleagues have been researching in the area of prevention and intervention of bullying in school-aged students for many years. During the Supportive Schools project, a randomised control trial which targeted bullying in secondary schools (Cross, Hall, Waters, & Hamilton, 2008), Cross noticed that cyberbullying was being reported as an issue by students. After three formative studies from 2007-2009, the research team received funding in 2010 to conduct a group randomised control trial to evaluate the effectiveness of a new program called the Cyber Friendly Schools program in reducing cyberbullying in secondary schools compared to standard cyberbullying intervention practices. Thirty-seven secondary non-government schools were randomly assigned to the intervention and comparison conditions, involving 3,500 students in Year 8 (ages 13-14). Using an online survey the students were asked about their cyberbullying experiences in a pre-test (beginning of Year 8), post-test (end of Year 9), and follow-up (end of Year 10).

The Cyber Friendly School program targeted pastoral care staff, teaching staff, students, and parents based on Bronfenbrenner's socio-ecological approach. Young people were involved in designing the teaching and learning intervention and Year 10 students who were trained as "cyber-leaders" helped teachers plan for and implement the program of whole-school activities. The study found the program slightly reduced student involvement in cyberbullying after 18 months of intervention but this was not sustained at follow-up.

One suggested reason for the small effect size was partial implementation failure. Teachers taught an average of only two to three 40-60 minute classroom modules out of a total of eight modules. Staff reported that they felt under-skilled to teach the program despite receiving training. Although the program had been modified from pilot testing with teachers, and was designed for teachers to facilitate the students' online self-directed learning, many teachers indicated they could not find the time in the curriculum/classroom to include this content as they were struggling to teach their allocated subject matter. Teachers' self-efficacy in this area therefore seems to need more professional learning and innovative methods to enable them to find time in the classroom to include these programs. An interesting finding was the Year 10 cyber leaders were so enthusiastic that many school pastoral staff were not prepared to support their suggestions as they were too adventurous. Perhaps staff need more preparation also in engaging with young people as co-researchers and collaborators.

Beyond Bullying

Following on from the Cyber Friendly School project, Cross' research team was granted funding in 2013 to conduct another randomised controlled trial of a universal and a targeted intervention to reduce mental health problems from all forms of bullying in school students. The study was designed to compare three groups of schools with students in Year 8 and Year 9; a high dose cluster of schools who will receive a universal intervention against bullying (including cyberbullying) plus a targeted intervention for students who persistently bully; a moderate dose condition with the universal intervention only and a low dose condition with care as usual. It is hypothesised that the high dose intervention schools will have significantly lower student reported anxiety and depression symptoms, as well as lower rates of bullying perpetration and victimisation as reported by school staff and students. The innovative part of this project is that it targets the individual perpetrator of traditional and cyberbullying. It has been shown that these students have well developed social skills and understanding and score high on social cognition (Bem, 1972; Erol & Erdogan, 2008; Rubak, Sandbæk, Lauritzen, & Christensen, 2005). However, students who bully have been shown to show low levels of empathy (Sutton, Smith, & Sweetenham, 1999) and thus interventions which appeal to the student's empathetic response to their victim, such as the Method of Shared Concern (Pikas, 2002), are often ineffective in discouraging the bullying. This project is instead trialling motivational interviewing, a cognitive counselling technique, which has been successfully used to reduce drug use, eating disorders, and violent behaviour in adolescents (Frey et al., 2011; Hettema, Steele, & Miller, 2005).

Research on Legal Interventions

Professor Campbell and her team won two grants from the Australian Research Council examining cyberbullying and the law in Australia. The first project investigated the incidence and consequences of cyberbullying among students and amongst teachers. Using a scenario method the understanding of cyberbullying among primary and secondary school students and teachers was investigated. Written anti-bullying school policies were analysed to ascertain their adherence to legal requirements. The second project is currently examining the knowledge and

attitudes of the school community to legal responses to cyberbullying and will produce legally-informed resources for use in schools.

Safe and Well Project

An innovative strategy for the prevention and intervention in cyberbullying that is being researched in Australia is the use of a social marketing campaign (Cross, Campbell, Slee, Spears, & Barnes, 2013). Social marketing attempts to change attitudes and behaviours for social good. It is based on the model of goal directed behaviour (Perugini & Bagozzi, 2001) that proposes that attitudes are antecedents for desires which provide direct impetus for intentions which are the key predictor of behaviour. Usually in an effort to reach young people about cyberbullying, the Internet is used to build adult created websites. However, none of these are evidence-based and so we do not know if young people are accessing them. Furthermore, most have been created without consulting young people (Cross et al., 2013).

Additionally, the messages are not usually in the media spaces where the young people interact. The Safe and Well Online project is exploring ways to rectify these issues by developing an online marketing campaign, designed by youth. A longitudinal study is being conducted to examine changes in attitude and behaviour together with an online panel to estimate campaign reach and impact. The first marketing campaign to counter cyberbullying was based on respectful behaviour online. It is called *Keep It Tame* (<http://keepittame.youngandwellcrc.org.au/>) and was launched in November 2012, running for four weeks online. The YouTube clip features an animated smartphone which becomes ugly and nasty if wrong decisions are made. The clip formed an interactive “banner ad” which literally popped up all over the Internet. The reach and impact of the campaign was measured by purchasing advertising space in social media websites such as Facebook and Club Penguin.

Another project from the Safe and Well Online project, which involves an innovative approach to cyberbullying, is a smartphone app called *Appreciate a Mate* (<http://www.youngandwellcrc.org.au/wp-content/uploads/2014/12/Young-and-Well-Annual-Highlights-2013-14.pdf>). The app instantly generates messages of appreciation so that young people can share positively online. It is aimed at strengthening self-esteem and enabling young people to start a positive cycle of online communication with their peers.

On a much smaller scale there has been interventions reported in Australian schools. One compared Year 6 students’ experiences of both traditional and cyberbullying who were in a school which taught Philosophy for Children (P4C) with a matched sample of students who attended schools which do not conduct this program (Tangen & Campbell, 2010). The Philosophy for Children approach (Lipman & Bynum, 1976) is based on both cognitive development and also, through participation in the “community of enquiry,” developing students’ social skills. The process involves children reading or viewing a stimulus, developing questions about the stimulus, and then participating in a dialogue with each other (Haynes, 2008). Although it was hypothesised that students at the P4C school would report significantly less bullying than the other students this was not the case. In fact there were more reports of face-to-face bullying in the P4C school. There were no differences in reported cyberbullying victimisation or perpetration between the two groups. It was hypothesised that while the P4C students learnt how to discuss and problem solve situations from story books they may not have transferred these solutions to their own lives. An interesting finding was that both cohorts of

students reported that at their schools adults were twice as likely to prevent face-to-face bullying than cyberbullying, as the students perceived that teachers were not generally as aware of cyberbullying taking place as they were of face-to-face bullying.

CONCLUSION

Unfortunately, despite these efforts, Australia's rate of cyberbullying in young people is similar to other countries as mentioned earlier. As Shariff (2015) has written, we seem to be no further ahead in our efforts to reduce cyberbullying. However, as cyberbullying is still half the prevalence of traditional bullying, perhaps our efforts have been able to at least contain cyberbullying if not yet to reduce it. There are many challenges for researchers of cyberbullying remaining. Until there is widespread agreement on the definition of cyberbullying then measurement difficulties will continue and prevention and intervention efforts will be hampered. Similarly measurement instruments need to be standardised, with the same cut-off points, definitions, and comparable age and nature of samples. More studies using a longitudinal design on consequences and risk and protective factors need to be carried out. In addition, community responses by the media and the legal profession need to be influenced by rigorous research. Finally, more large scale well-funded randomly controlled intervention studies to reduce cyberbullying are required.

Chapter 148

TEACHERS' PERCEPTIONS OF CYBERBULLYING IN IRISH SECONDARY SCHOOLS

Caroline Wheeler*
Trinity College Dublin

INTRODUCTION

School bullying is by no means a novel issue. Throughout the history of formal education systems, violence, to a certain extent, has been common place in schools (Aries, 1962). However, prior to the 1970s, school violence and bullying was not considered by teachers as an issue of foremost concern (Bayh, 1975; Gabriel, 1957; Phillips, 1932), and the cross-cultural perception that school violence is a major social and public health concern is a relatively modern occurrence (Chen & Astor, 2009; Flannery, Modzeleski, & Kretschmer, 2013; Li, 2007). For instance, during the 1930s, school bullying was not a concern for any of the newly-qualified teachers in England surveyed; rather they reported maintaining discipline, inadequate teaching equipment, social stance of the school, and violence between parents and teachers as their main matters for concern (Phillips, 1932). By the 1950s, teachers in England were mostly concerned about class control and class inspections rather than school violence (Gabriel, 1957).

However, the following decades saw an increase in school violence. By 1975, US School Superintendents noted an increase in school robberies (36.7%), student assaults on other students (85.3%), confiscation of weapons by school authorities (54.4%), school rape and attempted rape (40.1%), and school homicide (18.5%) in just three years between 1970 and 1973 (Bayh, 1975). By 1978, the U.S. congress mandated The Safe School Study, which found that 282,000 students were physically assaulted in U.S. secondary schools each month. At the same time, European countries were finding similarly high rates of school violence. In 1983, research conducted in Norwegian schools found that 15% of students were regularly bullied or acted as a bully (Olweus, 1991, 1993, 1995, 1997). The 1980s saw a rapid growth in research on school bullying throughout Europe (Brown & Winterton, 2010; Menesini et al., 2012; Olweus, 1991, 2011; O'Moore & Minton, 2009; Ortega et al., 2012; Wolke, Woods, Stanford,

* Corresponding Author's Email: cmkwheeler@gmail.com.

& Schulz, 2001), North America (Craig & Pepler, 2007; Good, McIntosh, & Gietz, 2011; Schneider, O'Donnell, Stueve, & Coulteret, 2012; Turner, Exum, Brame, & Holt, 2013), Asia (Chen & Astor, 2009; Ong, 2015; Zhou et al., 2013), and Australia (Rigby, 2000; Srivastava, Gamble, & Boey, 2013).

Notably, this wealth of research supports the view that school bullying is a global concern. Furthermore, findings strongly indicate that bullying is particularly persistent in schools during adolescence, and largely involves violence among students and their fellow peers. This increase in school violence and bullying continued to develop as a major concern for teachers around the world. By the late 1980s, research on teachers' perceptions of bullying had commenced, and teachers were reporting violence and bullying to be one of, if not the most serious issue within schools (Borg & Falzon, 1989; Kyriacou & Roe, 1988; Wilson, 1987).

In recent years, cyberbullying has become a major public concern for teachers throughout the world (O'Moore, 2012a). Cyberbullying has received increased international attention due to mass media reports of homicide and suicide cases, in which bullying was a precipitating factor (Dooley, Pyzalski, & Cross, 2009). Cyberbullying has received much attention from the research community with many survey-based studies being conducted (Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Monks, Robinson, & Worlidge, 2012; Raynor & Wylie, 2012; Schneider et al., 2012; Slonje, Smith, & Frisén, 2013), with results suggesting that there are a significant number of young people experiencing cyberbullying globally (Baek & Bullock, 2014; Hinduja & Patchin, 2014).

Regrettably, Ireland is no exception; with research findings showing that 13.9% of respondents aged 12 to 16 years reported that they personally experienced cyberbullying in recent months (O'Moore, 2012a). Furthermore, it seems that teenagers living in Ireland have an exceptionally challenging, byzantine relationship with cyberbullying. Research conducted by YouGov (2015) has found that Irish teenagers are more likely to be cyberbullied, with one in four Irish teenagers reporting that they had been cyberbullied, in comparison to one in five teenagers over 11 other countries surveyed. Of those Irish teenagers who had been cyberbullied, 45% reported feeling helpless, and one in four experienced suicidal thoughts (YouGov, 2015).

Bearing in mind that Irish youth suicide rates are one of the highest in Europe (European Child Safety Alliance, 2014), it is crucial that this issue is explored on both a scientific and governmental basis. Although there has been a growth in cyberbullying research over the past number of years, there remain many unexplored areas within the Irish context. One such area is the analysis of employed Irish secondary school teachers' perceptions of cyberbullying. Teachers are at the forefront of dealing with student bullying within schools (Byrne, 2015; Elledge et al., 2013; Li, 2008; Stauffer, Heath, Coyne, & Ferrin, 2012). All intervention programmes are primarily implemented by teachers, yet international research has found that although teachers acknowledge that cyberbullying is a major concern, they do not feel confident in dealing with it (Beringer, 2011; Eden, Heiman, Olenik-Shemesh, 2012; Li, 2008; Yilmaz, 2010).

BULLYING AND CYBERBULLYING: WHAT'S THE DIFFERENCE?

In order to truly understand cyberbullying, it is essential to review and appraise traditional bullying as both coincide to a certain extent. Olweus (2011) defines traditional bullying as "(1)

intentional negative behaviour that (2) typically occurs with some repetitiveness and is (3) directed against a person who has difficulty defending himself or herself" (p. 151). Although bullying has long been established as a school-based issue (Craig & Pepler, 2008), the growing demand and dependence of social networking and electronic communication has resulted in the topic of bullying shifting from the real world to the realm of the cyberspace (Mishna, Saini, & Solomon, 2009). Over the last decade, social interactions have changed quite drastically, owing to the exponential increase of electronic and computer based communication systems (Mishna et al., 2009). More youths are online now than ever before. In Europe, 96% of teenagers reported going online daily (Livingstone, Haddon, Görzig, & Ólafsson, 2011). According to the Internet World Stats (2014), 82.5% of the Irish population uses the Internet, with a 16.7% increase since 2010. Given that 84% of Irish teenagers own a Smartphone, it's becoming easier for these teenagers to access cyber technology at any time of the day (Thinkhouse, 2014). Although most online interactions are considered positive, such as academic support, social support, identity exploration, interpersonal and critical thinking, and cross cultural interactions (Gross, 2004; Jackson et al., 2006; Valkenburg & Peter, 2007), the dangers of social networking are also of concern (Shariff, 2009; Turel & Serenke, 2012; Valcke, Wever, VanKeer, & Schellens, 2011). One such risk is cyberbullying.

O'Moore (2012a) describes cyberbullying as "an extension of traditional bullying with technology providing the perpetrator with another way to abuse the target" (p. 210). Taking this into account, cyberbullying can take different forms including racist, homophobic, religious, transphobic, or cyberbullying of people with a disability or special educational needs (Li, 2008; Anti-Bullying Working Group, 2013). Although there are many similarities between traditional bullying and cyberbullying, research indicates that cyberbullying can be more problematic than bullying as not only can it follow the target wherever they go, the cyberbully can also remain sometimes anonymous (Ybarra & Mitchell, 2004a). Although research on the effects of cyberbullying in secondary schools is much more restricted than research on traditional bullying, researchers believe that the effects of cyberbullying can be similar and even more harmful than traditional bullying (Beran & Li, 2007; Bonanno & Hymel, 2013; Campbell, 2005; Ybarra & Mitchell, 2004b). These effects range from school absenteeism, reduced academic achievement, poor concentration, anger, frustration, depression, and in some cases suicide (Beran & Li, 2007; Bonanno & Hymel, 2013; Kowalski, Limber, & Agatson, 2008).

IRISH SECONDARY SCHOOL TEACHERS AND CYBERBULLYING

Considering the potential negative effects of cyberbullying, it is important for schools and teachers to take action to reduce cyberbullying within and outside of school (Stauffer et al., 2012). Not only are secondary school teachers in a vital position of authority, they are also responsible for the students' rules and behaviour (Jackson, Boostrom, & Hansen, 1993; Stauffer et al., 2012). According to the Association of Secondary School Teachers in Ireland (ASTI, 2012), the role of the teacher is to educate, respect, care for, trust, and exercise integrity. Furthermore, teachers should "work to establish and maintain a culture of mutual trust and respect in their schools" (ASTI, 2012, p. 6).

At present, research on teachers' perceptions of bullying and cyberbullying has been internationally examined, with results indicating that cyberbullying is an urgent and significant issue which needs to be directly addressed. Owing to the growing severity, character and adverse effects of cyberbullying, there is a call for educators to precede and initiate responses both nationally and internationally. In Ireland, responses have commenced, and an action plan on bullying was published by the Minister for Education and Skills in January 2013, which released a number of recommendations for consideration (Anti-Bullying Working Group, 2013). This contributed to the development of updated anti-bullying procedures for primary and post-primary schools (Department of Education and Skills, 2013). Moreover, the Joint Committee on Transport and Communications (2013) has also issued a report on tackling cyberbullying. Some of their recommendations include the establishment of a single body to govern social media content, the development of an EU wide response, appropriate training on cyberbullying for parents and teachers, and guidelines on managing cyberbullying for school principals.

Although research has investigated students' experiences, teachers' experiences and perceptions of cyberbullying within an Irish cohort (e.g., Corcoran, Connolly, & O'Moore, 2012; McNamara & Moynihan, 2010; O'Moore, 2012a), currently no such research on employed teachers' perceptions of cyberbullying in Irish secondary schools has been undertaken; with prior research focusing on students or pre-service teachers. This chapter will examine a study which adds to the research on cyberbullying by focusing on secondary school teachers' experiences and perceptions and concerns regarding cyberbullying. It investigates how secondary school teachers cope with cyberbullying, along with prevention strategies they have in place. In addition, it also investigates secondary schools' commitment to addressing cyberbullying.

METHOD

Design

In order to examine teachers' perceptions of cyberbullying in Irish secondary schools, a mixed methods research design was utilised (Hanson, Creswell, Clark, Petska, & Creswell, 2005). Prior research has indicated that there is a lack of mixed method research on teachers' perceptions of cyberbullying (Newey & Magson, 2010; Sassu, 2006). The quantitative component consisted of an online survey. An email was sent to every secondary school in Ireland, explaining the research and inviting teachers to participate. The questions were based on prior international research which examined teachers' perceptions of cyberbullying, and were edited to account for an Irish cohort of qualified teachers (Li, 2008; McNamara & Moynihan, 2010; Stauffer et al., 2012). Qualitative data was gathered by means of four semi-structured interviews with qualified secondary school teachers currently employed by the Irish Department of Education and Skills. The interview questions were also based on prior research, which examined teachers' understanding of cyberbullying (Mishna, Scarcello, Pepler, & Wiene, 2005). Descriptive-interpretive analysis was used to analyse the interviews (Elliott & Timulak, 2005). Ethical approval was granted by Trinity College Dublin for this study.

Participants

A survey examining teachers' perceptions of cyberbullying was sent to every secondary school in Ireland ($N = 721$) via email. One survey was to be completed by each school. Of the schools invited to participate, 82 completed the survey (see Table 1). Two were eliminated as they were unqualified (Higher Diploma students), leaving a response rate of 80 (11.1% participation rate).

Table 1. Demographic details of Quantitative Participants

		Frequency	Percentage
Gender	Male	29	36.3
	Female	51	63.8
Level of Education	Higher Diploma	39	48.8
	Masters of Education	34	42.5
	PhD/Other	7	8.80
Teaching Role	Class Teacher	15	18.8
	Curriculum Leader	1	1.30
	Anti-Bully Coordinator	2	2.50
	Home-School Liaison	1	1.30
	Pastoral Care/Chaplin	7	8.80
	Vice Principal	8	10.0
	Principal	35	43.8
	Guidance Counsellor	7	8.80
	Coordinator Position (i.e., SPHE)	4	5.10
Types of Secondary School	Male Secondary School	16	20.0
	Female Secondary School	17	21.3
	Co-educational Secondary School	47	58.8
	Secondary School	40	50.0
	Vocational Secondary School	10	12.5
	Community School	6	7.50
	Community College	24	30.0

The participants were fully qualified secondary school teachers currently employed by the Irish Department of Education and Skills. In total there were 39,103 pupils in all respondents' schools, with the mean number of 479.08 pupils ($SD = 252$). On average, participants were teaching for 19.5 years ($SD = 10.75$). The mean respondent age was 43.72 years ($SD = 9.86$). Four teachers were also interviewed with a semi-structured interview schedule concerning teachers' perceptions of cyberbullying (two female, and two male).

Materials

Quantitative Materials

Due to its recent emergence, measures for cyberbullying are limited (Li, 2008). However, due to the evident relationship between traditional bullying and cyberbullying, it has been

suggested that instruments used in traditional bullying research can also be used in cyberbullying research (Li, 2008). In turn, three surveys used in prior bullying research were utilised in this study (Li, 2008; McNamara & Moynihan, 2010; Stauffer et al., 2012). Adaptations were made so as to make the surveys suitable for an Irish cohort.

Li's (2008) survey, which focused on teachers' attitudes, was an edited version of a bullying survey, developed by Siu (2004), entitled 'Teacher's Attitude About Bullying Questionnaire'. It was edited by Li (2008) to address preservice Canadian elementary and secondary school teachers' attitudes about cyberbullying. McNamara and Moynihan's (2010) survey focused on teachers' experiences, perceptions and skills in addressing cyberbullying. A survey by Stauffer et al. (2012) which focused on prevention and intervention strategies for cyberbullying, was an edited version of a larger study which examined teachers' overall perceptions of bullying, whereby cyberbullying was viewed as a subset of bullying. It addressed qualified secondary school teachers, and it was formatted for an American population. The edited surveys were combined into one 59 item survey divided into three sections, consisting of a combination of Likert scale response options and open ended questions. The general awareness and skills in addressing cyberbullying scale consisted of 12 items, the tackling cyberbullying scale consisted of 21 items, and the prevention and intervention strategies scales consisted of 6 items.

Qualitative Materials

The interview schedule used in this study was based on prior research, and was adapted to be suitable for a fully qualified Irish sample of secondary school teachers (Mishna et al., 2005). It was also edited to address cyberbullying, rather than traditional bullying; thus the following cyberbullying definition was used; *An aggressive, wilful act carried out by an individual or group using electronic communication* (e.g., O'Moore, 2012b).

Procedure

Data was gathered concurrently for this research. On the 25th of February 2013, surveys were sent via email to each of the 721 secondary schools in Ireland. All relevant information regarding the research was provided in the email. Only one survey was required to be completed per school. Reminder emails were sent monthly over a four-month period. At the end of the survey teachers were invited to partake in an interview, and were asked to provide their name and contact details if interested. Each interview took approximately 40 minutes and each was recorded and transcribed verbatim. A debriefing form with a list of psychological support services in case of distress was given to each participant.

RESULTS

Quantitative Findings

General Awareness and Skills in Addressing Cyberbullying

Teachers' overall awareness and skills in addressing cyberbullying were examined (see Table 2 below). When asked "are you aware of a type of bullying called cyberbullying" all

teachers responded that they were Aware or Very aware of cyberbullying (100%). The majority of respondents (67.5%) reported that traditional bullying was the most prevalent form of bullying at their school. Of those who responded, 100% agreed that cyberbullying occurs mainly outside of the classroom, such as at lunch time or on the corridor. When asked, “how able are you to resolve cyberbullying incidents so everyone is content” just 38.8% felt that they were able to do so.

Concern about Cyberbullying

Findings suggest that teachers believe that cyberbullying is a problem in schools, with 93.8% respondents agreeing or strongly agreeing with the statement. Of the sample, 98.8% agreed that children are affected by cyberbullying, and 96.3% are concerned about cyberbullying. Results are displayed in Table 3.

Table 2. Teachers' General Awareness of and Skills for Cyberbullying: Main Findings

Statement		N	Percent
Awareness of cyberbullying	Aware/Very Aware	80	100
Types of bullying	Traditional	54	67.5
	Cyber	18	22.5
	Other	4	5.00
	None	3	3.80
Cyberbullying occurs in your school	Yes	67	83.8
	No	13	16.3
Able to support cyberbullied students	Incapable	13	26.3
	Capable/Very Capable	67	83.8
Able to resolve so everyone is content	Not able/Somewhat	37	46.3
	Unsure	12	15.0
	Able/Very Able	31	38.8

Note. Due to missing values, some percentages may not add up to 100%

Table 3. Proportion of Teachers' Concerned About Cyberbullying

Statement	Percent of Teachers' Responses					
	1/2	3	4/5	M	Median	SD
Problems in schools	1.3	5.0	93.80	4.61	5	.63
Children are affected	1.3	--	98.80	4.34	4	.69
I'm concerned	2.6	1.3	96.30	4.25	4	.61

Note: N = 80. Response options 1 = Strongly disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly agree.

Confidence in Dealing with Cyberbullying

In response to the statement “I feel confident in identifying cyberbullying” only 50.1% reported that they were confident. Similarly, in response to the statement “I feel confident in managing cyberbullying”, just 50% reported that they were confident. However, in response to the statement “If I knew cyberbullying was happening at a school, I would do something”, 96.2% of teachers reported that they would do something. Results are summarised in Table 4.

Prepared to Deal with Cyberbullying

In general, the vast majority of teachers (80%) felt that their university education left them unprepared to manage school cyberbullying. Overall, 91.3% indicated that they would like to learn more about cyberbullying during their training, and 70.1% agreed that training in cyberbullying is just as important as other topics covered in their university education.

Importance of School Commitment

Teachers’ attitudes concerning the importance of school commitment were examined. Results found that teachers were in favour of most statements regarding school commitment, such as developing school cyberbullying policies (97.6%), use of professional development days to train staff on cyberbullying (93.8%), use of cyberbullying curriculum (91.3%), and the use of classroom activities to address cyberbullying (90%). However, the majority strongly disagreed with discussing cyberbullying with parents (63.8%), addressing cyberbullying at school assemblies (46.3%), and using television and other media to discuss cyberbullying (55%).

Table 4. Proportion of Teachers Confident in Dealing with Cyberbullying

Statement	Percent of Teachers’ Responses					
	1/2	3	4/5	M	Median	SD
Confident in identifying	17.5	32.5	50.1	3.44	3.5	.991
Confident in managing	20.1	30.0	50.0	3.34	3.5	.967
I would do something	0	3.80	96.2	4.68	5.0	.546

Note: N = 80. Response options 1 = Strongly disagree, 2 = Disagree, 3= Neutral, 4 = Agree, 5 = Strongly agree.

The Impact of Cyberbullying

The majority of teachers reported that cyberbullying has long lasting negative effects (88.8%). Almost all teachers (98.8%) were supportive of implementing a formal bully prevention programme in their school. Furthermore, respondents reported that cyberbullying does not toughen kids up (96.3%), nor does it prepare them for life (85.1%).

Prevention Strategies

Increased parental involvement was found by teachers to be the most helpful prevention strategy for cyberbullying, with 96.3% agreeing that it would be Helpful or Very Helpful. Teachers were asked to share there ideas on what teachers need to manage cyberbullying. Of the 75 teachers (93.75%) who responded, 27 teachers (36%) suggested training and in-services on cyberbullying. Fourteen teachers (18.7%) endorsed increased training in information technologies; specifically one Vice Principal, M, with 30 years teaching experience, reported that “Many teachers are so unfamiliar with social networks that they don’t even share the language used by students . . . and therefore are at a loss when it comes to dealing with incidents . . . some teachers are wary of technology and it’s a very slow process to bring them on board to adopt it in their classroom.”

Teachers were also asked to share their ideas on what makes it difficult to address cyberbullying. Of the 75 teachers who responded (93.75%), the majority (N = 13; 17.3%) recognised its occurrence outside of school. Of the sample, 12 teachers (16%) referred to the lack of training, 12 teachers (16%) addressed the prevalence of bystanders and secrecy, eight

teachers (10.7%) addressed the lack of parental supervision, and seven teachers (9.3%) addressed the lack of protocols. Only two teachers (2.7%) mentioned lack of school initiative, and lack of training in technology (2.7%).

Qualitative Findings

Qualitative findings obtained from teachers allow for better understanding of teachers' perceptions of cyberbullying within Irish secondary schools. Details of the sample interviewed is displayed in Table 5. The domains, categories and themes were identified, and are displayed in Table 6. The section that follows discusses the most prominent themes in detail.

Gender Differences

All teachers agreed that female students' cyberbullying is more malicious, intentional and more frequent than male students. J reported that

"I think that, that it's more sorta female linked, maybe I'm wrong on that but that would be my perception that girls tend to use it more than the fellas."

Table 5. Demographics for Qualitative Participants

Name	Male/Female	Location	Students	Years Teaching
Á	Female	Urban	700+	3 years
R*	Female	Rural	350+	10 years
J	Male	Urban	600+	10 years
E	Male	Urban	600+	10 years

* R is the schools anti-bullying coordinator

Table 6. Domains, Categories and Themes Identified in Descriptive-Interpretive Analysis

Domain	Category	Theme
General Awareness of Cyberbullying	Definition	Misuse of mobile phones (1/4)
		Misuse of social networks (3/4)
	Gender Divide	Nature of female cyberbullying (4/4)
		Nature of male cyberbullying (4/4)
Exposure to Cyberbullying	Disclosure	Student disclosure (3/4)
		School management disclosure (1/4)
		Witnessing cyberbullying (1/4)
		Peer victimisation (1/4)
	Reasons for Cyberbullying	Being different (1/4)
		A sense of belonging (1/4)
		Resentfulness (2/4)
	Effects of cyberbullying	Short and long term effects (4/4)
		Fear of victimisation (1/4)
		Invulnerability (1/4)

Table 6. (Continued)

Domain	Category	Theme
Specific Responses to Cyberbullying	Parental and School Responses	Proactive responding (2/4)
		Passive responding (2/4)
	Training/Policies/ Programmes	Insufficient training on cyberbullying (4/4)
		Anti-cyberbullying school policy (4/4)
		Role of parents and communities (4/4)

By contrast, all four teachers agreed that male students use traditional forms of bullying more often than female students. Furthermore, all four teachers agreed that male students can often be unaware that they are cyberbullying, and are unaware of the damage that they are doing. E explained how oblivious boys can be when it comes to cyberbullying.

“I find, boys in particular bully, and then say I was only messing, and they really do feel that it was only messing, but often you know, in this only messing some of the . . . most horrendous things are said.”

Short and Long Term Effects

All teachers interviewed agreed that cyberbullying affects students both in the long term and short term. E went on to discuss how cyberbullying can have numerous short term and long term effects

“Students can become introspective, and you know just feeling deeply hurt about it. Others will become quite angry, and will lash out . . . in the long term, students who don’t disclose may suffer from psychological harm. It’s the children who don’t say anything, who suffer in silence, who never disclose. They’re the ones I think who are more likely to suffer more long term damage, and maybe psychological damage into the future because for them it was never resolved.”

Proactive and Passive Responding

All teachers agreed that some parents are very proactive in protecting their child from cyberbullying. R noted that parents often set up a Facebook page to monitor their child’s online activity.

“A lot of parents insist on being a friend of their son or daughter, or they insist on having controls to the profile.”

Furthermore, two teachers reported that some parents are somewhat ignorant and oblivious to cyberbullying. E in particular reported that some parents believe that cyberbullying doesn’t exist.

“There will always be a small minority who really don’t believe it’s happening, and don’t believe it’s of any great consequence. I mean . . . I had a parent who told me last year that, you know, boys will be boys.”

Furthermore, A noted that some parents will use their Facebook page to cyberbully alongside their child.

"The other girl's mother was on Facebook, even writing stuff about her . . . it's another story and parents are even getting involved in the cyberbullying, let alone trying to sort it out."

Insufficient Training on Cyberbullying

All four teachers reported that they had received insufficient, or no training on cyberbullying. Although two teachers received training on cyberbullying, they reported that it was too trivial and general, and they would like to receive more specific training for cyberbullying. R, for instance reported that she would like to attend training on strategies for cyberbullying, and how to actively seek cyberbullying as

"when students see that you're actually actively looking out for bullying, that makes a huge difference as well, there's a change in the behaviour."

A, who was newly qualified and had not received training in cyberbullying, reported that she felt ill-equipped to deal with cyberbullying. She further reported that senior teachers were more prepared for dealing with it.

"At a senior level . . . They've more experience with it but at a teacher's level and form teacher's level . . . not so much."

Role of Parents and Communities

All teachers reported that cyberbullying is a problem. J noted that although by nature we will always have bullies, the development of cyberbullying has established an easy avenue into bullying, encouraging students once unlikely to bully to become involved in the behaviour.

"I think the development within information technology has added. It's another avenue into bullying, and it's probably an easy enough avenue. People who mightn't have traditionally bullied, might have had bullying tendencies. It's a lot easier for them to go and, and bully due to cyber technology".

E noted that cyberbullying enhances the opportunity of prolonging bullying, whereby students can be bullied 24/7.

"It's 24/7 it, it you know? I used to come home from school, and tell my mate I'd meet him at the corner at 5 o'clock, you know because neither of us would have phones in our houses. You know? And there wasn't this need for constant contact. They have this need for constant affirmation and contact with each other and they use that type of media to also bully each other . . . So it seems to be a constant".

All teachers noted that they need more training on cyberbullying. Specifically, A noted that teachers need training on what to do when they are approached by a child who is being cyberbullied, so that every child is given the same opportunities.

"There should be some sort of in-service or more talks on cyberbullying and how to actually deal with it because yesterday I actually didn't know what to do . . . teachers who aren't form teacher should have some sort of idea of what to do, because any sort of a

student can come to you . . . everyone in the school should have some sort of idea of what to do.”

Additionally, all teachers interviewed agreed that parents and communities have an important role in tackling cyberbullying. J noted that teachers and schools should not take sole responsibility of tackling cyberbullying, rather parents and community need to take action.

“Society will often feel, there’s an issue in society, throw it onto the schools. I think what schools are finding now is that we’re overloaded with stuff. That other agencies and parents and that have to take responsibility. Schools have a role, but we can’t have ultimate roles.”

CONCLUSION

The overall aim of this study was to examine secondary school teachers’ experiences and perceptions of cyberbullying within the Irish cohort. Given that cyberbullying is a developing global issue, and given that there is a paucity of research on teachers’ perspectives on cyberbullying in Ireland, this research gives an insight and understanding on what the current situation is like in Irish secondary schools. The insights gained from this research go some way towards highlighting the needs of Irish teachers in the current school climate; indicating some of the challenges they face, the supports they require, and the efforts they are currently making to best serve their students. The survey in the current research was conducted online, and therefore only accessed Internet users. This has important implications given the nature of the study, and future research should strive for a more representative sample of teachers. In addition, none of the teachers interviewed reported that they were bullied or cyberbullied as children or adolescents. Prior research has found that personal experiences of bullying or cyberbullying may affect one’s responses to school cyberbullying (Kallestad & Olweus, 2003; Mishna et al., 2005). Future research is necessary to develop our understanding of cyberbullying in Ireland and internationally. Based on prior research, it is recommended that future studies examine gender differences in teachers’ perceptions of cyberbullying in Irish secondary schools. Evidence to date indicates that there is a relationship between pre-service teachers’ gender and their confidence in dealing with cyberbullying; with male pre-service teachers being more confident (Li, 2008; Yilmaz, 2010). In addition, other possible correlates of teacher attitudes could be examined, such as personal attributes and empathy. Furthermore, it is not only teachers who provide care for students when in a school environment, and therefore inclusion of school principals, educational psychologists, and school coordinators in future studies could provide valuable knowledge.

Although cyberbullying is a recent phenomenon in Ireland, findings from both surveys and interviews support previous research indicating that cyberbullying is a complex and multifaceted issue embedded within secondary schools (e.g., Beran & Li, 2005, 2007; Cassidy, Brown, & Jackson, 2012). Whilst we have updated guidelines that require schools to address the issue of cyberbullying in their anti-bullying policy, there is a need to develop resources and supports for teachers. In general, the results from both surveys and interviews found that teachers are concerned about cyberbullying, and feel committed to managing and handling it, but are underprepared and lack confidence in dealing with it. Considering that teachers’

confidence can help students develop a sense of security and safety (Boulton, 1999), it is vital to develop teachers' knowledge and skills about cyberbullying, which in turn, will increase their confidence. As cyberbullying incidents predominately occur outside of Irish secondary schools, teachers emphasise their concern regarding parental and community awareness of cyberbullying. Therefore, it is vital that both parents and communities in Ireland become more familiar with the characteristics and prevention strategies of cyberbullying, especially considering that more Irish youth are using technology than ever before. In order to best support schools to provide for the educational, physical, and psychological well-being of children and young people, we need to implement a collaborative, whole school and community approach to traditional bullying and cyberbullying with provision of adequate training, management, and resources at school- and societal-level.

Chapter 149

CONCLUDING THOUGHTS: WHERE ARE WE NOW AND WHERE TO NEXT?

Lucie Corcoran*

School of Arts, Dublin Business School, Dublin, Ireland

INTRODUCTION

This book comes at an important juncture for young Internet users, families, teachers, cyberbullying researchers, practitioners, and policy/law makers. Cyberbullying is high on the education and psychological welfare agenda internationally. In fact cyberbullying is recognised by many as a key challenge facing today's youth - although still regarded by many as a "first world problem" rather than a pressing matter. There is a wealth of literature pertaining to the issue of cyberbullying and we see national and cross-national initiatives aimed at developing research and practice in order to best serve young people, schools, and communities in their interaction with the cyber world. This chapter reviews some of the key issues raised throughout this book and attempts to draw some conclusions regarding a range of issues, from fundamental considerations in relation to how we conceptualise cyberbullying, to important issues we must reflect on so as to intervene effectively; many of which have been highlighted by the authors throughout.

BACK TO BASICS: DEFINITIONS, MEASUREMENT, AND DETERMINANTS

The early chapters in the book examine the development of cyberbullying research, the current arguments regarding definitions, international prevalence rates, and the role of gender. Peter K. Smith and Fethi Berkkun examine the development of cyberbullying research since its beginnings with the emergence of the term 'cyberbullying.' They refer to four phases of development of traditional bullying research from the 1970s: (i) beginning with Olweus' initial

* Corresponding Author's Email: lucie.corcoran@dbs.ie.

examination of school aggression which led to the creation of a self-report measure and school-based intervention; (ii) this was followed by international surveys of school bullying and intervention efforts outside of Norway, whilst the concept of bullying was expanded to encompass relational bullying; (iii) following this, school bullying became established as an international research program and in Finland Salmivalli and colleagues began to look at the various bystander roles; (iv) this leads to the most recent phase which has focused on cyberbullying and began around 2004 with emphasis on text and email bullying. Smith and Berkun undertook to chart the evolution of cyberbullying research with a literature review of journal articles from 1990 to the end of 2015 where the abstract is written in English and the article is focused on cyberbullying, victimization, or harassment. This review highlights the recent growth in academic literature which focuses on bullying and cyberbullying. Smith and Berkun credit availability of funding with some of the recent growth in European studies, whilst also highlighting the parallels between the access to cyberspace and the emergence of literature. It is also evident from this review that the research has tended to be quantitative and cross-sectional rather than longitudinal or qualitative. Smith and Berkun argue that there is a need for more qualitative research; a move away from the more traditional and perhaps psychological approach to bullying research.

These articles have covered a range of relevant issues, including definitional and measurement considerations such as the various perspectives on how best to label, define, and conceptualise cyberbullying, and the variety of available measures for assessing the incidence of the behaviours. Despite the inconsistencies across study methods, it is estimated by the authors that occasional occurrences may be reported by over 20% of research participants, but that serious, recent, or repeated incidents are generally reported by around 5%. Analysis also revealed that cyberbullying is experienced amongst a wide variety of ages, but seems to peak in adolescence. Smith and Berkun suggest that the increasing cyber access among younger age groups may come to be reflected in cyberbullying research over time. When examining gender differences, they found that age is an important consideration, with boys possibly becoming more involved as perpetrators than girls as they get older. Furthermore, it is proposed that cyberbullying via social networking may be more appealing to girls as it facilitates reputation damage. Studies which include a cross-cultural comparison or focus on disability and minority groups are rare within the literature according to this review, whereas research focusing on risk factors, or predictors, or outcomes of involvement in cyberbullying occurred more frequently. Around one fifth of studies have also focused on the peer group and group norms, whereas other researchers examined the roles of parents, teachers, and siblings. A small proportion of studies reviewed had focused on legal implications whilst studies of coping strategies, resources, and interventions were somewhat better represented. Overall this chapter provides an up-to-date account of the face of cyberbullying research, and indicates the key areas that require further examination.

Taking a narrower focus, Pauline K. Hyland, John M. Hyland, and Christopher Alan Lewis examine the conceptual issues and definitional considerations regarding cyberbullying, and also discuss the appropriateness of the term cyber aggression as an alternative label. Their review of the main theories and types of aggression highlight the complexity of aggressive and bullying behaviour and the possible factors which contribute to the problem; an important consideration for those hoping to counter it or intervene effectively. They position bullying as a sub-type of aggression which is generally agreed to be intentional, repetitive harm doing which is also characterised by a power imbalance; components they argue are more important

to focus on than the name or label provided by different cultures. Hyland and colleagues go on to examine the appropriateness of the term cyberbullying and the applicability of the criteria of traditional bullying to this cyber-based aggression. Moreover, they examine the overlap between these distinct yet related behaviours and emphasise the relevance of operational definitions for measurement of cyberbullying; highlighting the merits of a multiple-item scale as opposed to a global question. Finally, the authors examine the usefulness of the label and concept of cyber aggression rather than persisting with the term cyberbullying and the criteria which that label entails. This chapter offers an important overview of some of the fundamental considerations with which researchers must engage before undertaking to extend the knowledge in this field.

Irene Connolly echoes some of the points made by Hyland and colleagues, as she highlights the importance of definitional and measurement issues when reviewing current knowledge of cyberbullying prevalence rates. Also making reference to the evolution of cyber technology, this chapter indicates how the Smartphone has led to the merging of Internet and mobile telephone media. Connolly also discusses the importance of online anonymity (an important aspect of the cyber world) which, she says, facilitates "... an almost dual Bruce Banner/the Hulk personality ..." where individuals who conduct themselves in a polite manner face-to-face, abuse others online. Furthermore, Connolly indicates the importance of achieving an appropriate definition for standardising national and cross-national prevalence rates, as a standardised definition could facilitate standardised methodologies; a consideration highlighted by Smith and Berkkun when considering the inconsistent prevalence rates found internationally. Connolly argues that, with the emergence of cross-national cyberbullying research, it is important to examine the methodologies which can affect the prevalence rates obtained. Methodological variations include: the provision of a cyberbullying definition and listing of exemplary behaviours; the labelling/conceptualisation of the phenomenon (e.g., cyberbullying, Internet harassment); the timing of the studies in terms of how they relate to technological advances such as the development of the Smartphone; age groups included in samples; the time referencing of questions (e.g., experiences in the last month, or ever in school); and methods of collecting data and sampling approaches (e.g., offline convenience sampling). Furthermore, Connolly highlights the fact that cyberbullying rates are often examined as one/two item measures, based on yes/no responses; an approach that could create difficulty as a simple yes/no response may not be adequate for a complex construct such as cyberbullying. An important conclusion that is drawn towards the end of this chapter is that it is important for researchers to turn their attention towards the duration and length of time between cyberbullying incidents so as to gain better insight into the potential effects, whilst development of valid and reliable measures can improve the quality of literature.

Addressing another fundamental issue within the literature, Raúl Navarro, Santiago Yubero, and Elisa Larrañaga provide a current review of the findings regarding gender as it relates to cyberbullying; a variable measured in many studies on the topic of bullying or cyberbullying. Setting out the boundaries of the term gender, Navarro and colleagues indicate that it is more than our biology; it is a social category which informs our social world, including stereotypical beliefs about personality traits and roles. This has important implications for aggressive behaviour as it may be considered adaptive for males, whilst for females it may be seen as something to be suppressed. Additionally, such gender norms may contribute to the increased risk of victimization associated with being female and therefore having a less powerful position in society and indeed a disadvantaged position in the cyber world. Navarro

and colleagues highlight the common claim that males and females are inclined to engage in different forms of aggression; with males tending more towards verbal and physical bullying, and females engaging more in relational bullying. Although this gender difference has been rationalised by arguments such as the superior social intelligence of young girls contributing to more skilled manipulation, the authors make reference to research which contradicts this trend. Meta-analytic research has indicated that males engage in every form of aggression to a greater extent, and the authors suggest that “People mostly use various types of aggression depending on surrounding demands.”

In their own research, Navarro and colleagues found that, amongst Spanish students, males were more frequent perpetrators of cyberbullying than females. Similar to the points made in previous chapters, the lack of consistency in approaches to cyberbullying research makes analysis difficult. However, they found that males were more inclined to send threatening or insulting messages by mobile phone, and more likely to be victims of a video or pictures by mobile phone when someone hits or hurts them. Navarro and colleagues argue that their findings and international research suggest that in cyberbullying there is no clear difference in prevalence of involvement between males and females. It seems that females are more likely victims of cyberbullying than traditional bullying, and males are inclined to perpetrate and suffer cyberbullying that contains humiliating images or contains physical aggression. Males also have a greater tendency to send more sexual or pornographic images; which is a form of victimization to which females are more exposed. Therefore, they argue that these forms of sexual and gender harassment require more attention from researchers.

In their own research, Navarro and colleagues found that all of those who carried out cyberbullying were aware of the gender of the targeted person. Furthermore, they found that cyberbullying was directed at significantly more people of the same sex than of the opposite sex. However, males were more likely to report involvement in cyberbullying that concurrently included males and females. The authors state that males use more types of indirect and relational aggression when targeting females, and they suggest that the anonymity and differing social norms of cyberspace may contribute to higher rates of female-directed bullying. Furthermore, it is proposed that there is a need to examine romantic relationships because cyberspace is an important component in developing and maintaining intimate relationships, and therefore could be used as a vehicle to assault and control partners. Navarro and colleagues express concern about the stereotypical view among both male and female Spanish students that females are worse, more subtle and more harmful, despite the findings to the contrary. This in-depth analysis of gender roles is one which should be given real consideration as we move forward in research.

APPROACHING CYBERBULLYING WITH A DIFFERENT PERSPECTIVE

Jolanta Burke and Stephen Minton offer an alternative view to much of the research to date, by inviting readers to examine traditional bullying and cyberbullying from a positive psychology perspective. They argue that, in light of the modest success of many existing anti-bullying interventions, a different approach is warranted. Burke and Minton highlight the pattern in bullying research to date which has focused largely on deficits and ill-being; examining the negative effects of involvement and the negative characteristics associated with

perpetration. With regard to measurement of well-being, the “body-builder” approach has been common. Measures of well-being have allowed measurement of the individual levels of their assumed sub-components; therefore “overall” well-being scores can be calculated which comprise the sum of sub-componential scores. In this way it could be argued that to enhance well-being, each sub-component can be increased. This chapter examines some of the key theories of well-being and highlights the philosophical underpinnings. For example, Subjective Well-Being theory, is described as deriving from hedonic philosophical tradition and focuses on life satisfaction, pleasant affect, and unpleasant affect, whereas Psychological Well-Being theory has links to the eudaimonic tradition and focuses on self-acceptance, positive relations, autonomy, environmental mastery, purpose in life, and personal growth. Furthermore, the Authentic Happiness Model includes both hedonic and eudaimonic elements of well-being; the components focus on the life of pleasure, engagement, and meaning. Burke and Minton argue that in order to measure well-being, it is important that we assess positive states of well-being as well as absence of negative states; drawing on research which suggests that there is more to positive affect than constituting the opposite of negative affect. For instance, some research indicates that ill-being and well-being can co-exist within a person. The authors argue that distinguishing well-being from ill-being can facilitate further insights into bullying and cyberbullying, but can also protect against researchers drawing flawed conclusions from the research. Burke and Minton suggest that such a broadening of the research may enhance the efficacy of anti-bullying and anti-cyberbullying intervention efforts.

Following this, Stephen James Minton offers an important, different perspective on cyberbullying behaviour; making reference to the idea of ‘distance’ in a literal or psychological sense. The role of physical proximity was an important variable in Milgram’s experiments with compliance being predicted by physical proximity to the learner and/or the experimenter. Minton also discusses the importance of proximity to weapons and how this relates to our inhibitions to use them. This can have self-destructive consequences as it is argued that our development of weaponry has outstripped our progress in relation to ethical and humane treatment of others. This chapter also argues social distance can also contribute to the lack of responsibility we feel for our aggressive behaviours. Such social distance can be facilitated by seeing others as something different to, or less than, human. Furthermore, Minton highlights the influence of de-individuation and the bystander effect on our response. By utilising decreased physical proximity and increased social distance we can morally distance ourselves from our aggressive behaviours. In this way, it is suggested, we can conduct hostile acts and bear the consequences. The relevance of this to cyberbullying is important to consider, and Minton argues that physical proximity and social distancing perhaps make it easier to abuse someone online and then justify our actions later compared with attacking someone face-to-face.

Furthermore, Minton highlights the fact that research has shown cyber aggression to be positively associated with moral disengagement and moral justification. This chapter offers Stephen James Minton’s reflections on the next possible steps for cyberbullying research. He argues that, in light of the various debates regarding conceptualisation of cyberbullying, there is a need to examine meaning-making used by young people with regard to their online activity and that this might best be achieved via qualitative methodologies. Ultimately this chapter concludes with the following recommendations: (i) there should be further exploration of the role of physical proximity and social distance as it relates to cyberbullying; (ii) young people’s meaning-making with regard to cyberbullying and cyber aggression should be examined

utilising qualitative methods. Both chapters provide thought-provoking suggestions which differ from previous literature.

THE IMPORTANCE OF CROSS-NATIONAL RESEARCH AND CULTURAL CONTEXT

Cyberbullying research has been furthered by funded cross-national collaboration. Brian O'Neill and Thuy Dinh provide a review of the main findings from EU Kids Online research and examine the contribution of cross-national large scale studies to cyberbullying literature. With regard to policy development, they state that the first phase of policy interventions focused largely on addressing potential harm and was based on assumptions about risk posed by the Internet. However, due to the lack of adequate evidence to inform policy, the EU Kids Online was established as a research network with the purpose of developing knowledge regarding children's online opportunities, risks, and safety. In its first stage (2006-09) a comparative analysis of the existing evidence base carried out by a network of European researchers led to development of a typology of content, contact, or conduct risks and opportunities that arise for young people in cyberspace. Furthermore, this first stage promoted the facilitation of children's confident and flexible Internet use. O'Neill and Dinh go on to describe phase 2 of the programme, which involved a major quantitative survey of 9-16 year olds across 25 European countries; the purpose of which was to develop knowledge about children's and parents' experiences and practices in relation to risky and safer use of online technologies so as to inform efforts to develop a safer online environment for children. The data collection focused on: exposure to sexual images; sending/receiving sexual messages; bullying and harassment; and meeting strangers. Echoing the same point made in previous chapters, O'Neill and Dinh highlight the challenge of using terminology for bullying (not an easy term to translate) in a cross-national study. Findings indicated that face-to-face bullying was more prevalent than online bullying, that girls and older adolescents reported higher levels of victimization, and an overlap between traditional bullying and cyberbullying was evident. Furthermore, O'Neill and Dinh report that those involved in online bullying showed greater psychological vulnerability than those not involved. Also, compared with perpetrators of traditional bullying, cyberbullies were more inclined to engage in risky online behaviours, spend more time using the Internet, and also felt it was easier to be themselves online. When examining participants who were involved in online bullying, higher SES was linked to increased involvement in bullying, whilst lower SES was linked to greater involvement as a victim. Importantly the authors indicate that lower SES was related to lower use of certain coping strategies such as altering Internet settings, or deleting messages. The authors also note some cross national differences, with certain countries characterised by a parent-child gap in agreement on whether the child has been victimized online. For instance, in Norway, parents are more likely to report that a child has been victimized even when the child does not, whereas in Romania, for example, a child is more likely to say he/she has been victimized than the parents are. EU Kids Online categorised countries on the basis of their levels and types of Internet use and risks as follows: Lower use, lower risk; Lower use, some risk; Higher use, some risk; and Higher use, higher risk. An important insight offered by the authors is the finding that cyberbullying is more prevalent in countries with a higher prevalence of bullying in general, rather than being more prevalent in

places where the Internet is more established. It is interesting to consider the argument proposed by Navarro and colleagues, as O'Neill and Dinh report that boys and girls were equally likely to bully online, but boys were more likely to bully offline. The authors also propose that we can make a distinction between those who bully online and offline when we examine their gender, and behaviour and attitudes associated with the Internet. They propose that those who are involved in bullying online either as a perpetrator or victim are also the most vulnerable offline and require support in both the cyber world and the 'real' world. A more recent cross-national study called Net Children Go Mobile has found that, within a sub-set of the countries involved in EU Kids Online, although prevalence of bullying has not increased since the EU Kids Online survey, cyberbullying has become more prevalent than face-to-face bullying and takes place most frequently on SNS. They argue that the rise in cyberbullying has been amongst females and amongst the youngest age group. O'Neill and Dinh conclude that there is value in research like EU Kids Online as a way of providing "... a solid baseline for policy development and where necessary targeted intervention."

Seung-Ha Lee provides a chapter on cyberbullying from a South Korean perspective. It is noted that cyberbullying has been highlighted in South Korea due to high profile cases of suicide following victimization, and more recently the government have recognised cyberbullying as a sub-type of school bullying. This hierarchical categorisation of cyberbullying is similar to those approaches outlined by Hyland and colleagues when examining definitions and conceptualisations of the phenomenon. Also, echoing some key points made in previous chapters, it is noted that in a South Korean context, a variety of terms are used to describe bullying-type behaviours such as *gipdan-ttadolim* (group isolation) and *hakkyo-pokryuk* (school violence), and that such labels are sometimes used interchangeably. Similarly, a number of labels are used for cyberbullying; *cybergorophim* (cyber-harassment), *cyberttadolim* (cyber isolation), *cyberpokryuk* (cyber violence), and *cyber wang-ta* (a socially excluded person in cyber space, or social exclusion in cyber space). Furthermore, even within South Korea, there is a lack of agreement as to the appropriate definition. Seung-Ha Lee highlights the complexity and array of cyber-based aggression (including *cybergangyo* or *wifi shuttle*) and how they relate to school bullying. Indicating efforts to develop an understanding of such problems, it is reported that the South Korean government has conducted a bi-annual data collection amongst school pupils to assess the levels of *hakkyo-pokryuk*. Fortunately this has indicated that being a recipient of school violence has been quickly decreasing in the last 2-3 years. Again emphasising a point made by Irene Connolly, Seung-Ha Lee argues that the varying prevalence rates of cyberbullying found in South Korea may be attributable to varying methodologies.

Lending some findings to the earlier discussion of gender differences, this chapter indicates that in general, boys were more likely to perpetrate *cyberpokryuk*. Furthermore, more boys were involved in a number of specific types such as cyber defamation and cyber sexual abuse, whereas females were more likely to perpetrate *cyberttadolim* and with regard to cyberexclusion (or *cyberbaejae*), a higher percentage of perpetration emerged for girls. Furthermore, boys were found to be more likely to be victimized by *cyberpokryuk* and across a variety of forms. However, cyber sexual abuse was more common in girls; a particular form that requires further investigation if we are to consider the analysis provided by Navarro and colleagues. Seung-Ha Lee also suggests that girls may experience relational cyber aggression more frequently than boys. Gender differences were also found to vary across school levels.

It is evident from these studies that perpetrators were most inclined to engage in cyberpokryuk “for fun” or to “upset the victim.” This has important implications for appropriate prevention and intervention as it would suggest a certain lack of emotional empathy. However, it is stated that many also felt negative feelings as a result of their behaviour. Those who are victimized report a variety of responses including getting revenge, and demanding removal of content. Telling a school teacher was an uncommon response to victimization. The least frequent reaction was to report to the police or the bullying and cyberbullying intervention centre. Sharing the incident with friends or family was considered to be a useful coping strategy to stop the problem. Whilst telling teachers was effective at elementary school level, it was not so helpful at higher school levels. This has important implications for successful intervention and reflects a need for either attitudinal change or alternative strategies with older age groups. Another finding reported by Seung-Ha Lee was that almost half of those who witnessed victimization did nothing to help because they thought of it as “nothing” or did not know what to do. Again there are important implications here, particularly in relation to bystander apathy; bringing to mind the relevance of social and psychological distance that Stephen James Minton discussed. South Korean research has identified correlates of cyberbullying involvement at an individual level (e.g., aggression, impulsiveness), at a home level (e.g., parenting style, violence in the home), and at a school level (e.g., school satisfaction, delinquent peers). Efforts to counter cyberbullying have been undertaken; for instance The Hakkyo-pokryuk Prevention and Intervention Act in 2012 requires that a school must assemble the committee of hakkyo-pokryuk if an incident is reported. The committee will deliberate on the incidents, and decide an appropriate course of action such as punishing the bully or facilitating conciliation between a victim and bully. In addition, the Ministry of Education has services which can facilitate reporting or advice seeking following an incident. This is supported via cyber technology and although it protects anonymity, it can also be linked to the class teacher. Seung-Ha Lee also recommends that there is a need to develop a healthy Internet culture, where ethics are emphasised. Evaluation of current efforts is also recommended.

COPING AND INTERVENTION

Francine Dehue, Trijntje Völlink, and Nicole Gunther discuss important considerations when developing and implementing stand-alone interventions. They begin by restating some of the main points made in previous chapters; for instance that there is still debate regarding some fundamental questions in the cyberbullying literature; such as the prevalence of involvement or witnessing of cyberbullying, whether we should regard it as a form of traditional bullying and therefore the two should be addressed together, whether cyberbullying has been over-rated in terms of prevalence and impact, and whether it is a cause or consequence of compromised well-being. Similar to other chapters, the authors refer to the various methodological inconsistencies that hamper assessment of prevalence; an important consideration when identifying the population at risk for prevention or intervention purposes. With regard to measurement, Dehue and colleagues suggest that, when attempting to identify those at whom an intervention programme to stop cyberbullying and reduce its effects would be aimed, a subjective direct assessment is suitable, as this would indicate those who consider themselves to be involved. In addition, they recommend that, for stand-alone ICT

interventions it is better to use a short time frame for assessment of involvement. Smith and Berkun had highlighted the tendency towards cross-sectional studies, and Dehue and colleagues also emphasise this as it impacts on the possibility to draw cause and effect relationships between variables.

This chapter highlights the need to develop our understanding of coping strategies, so as to facilitate behavioural change programmes which will be effective and to support reduction of victimization and its associated effects. The authors indicate the importance of contextual factors such as relationship with the perpetrator and the perception of control over the situation. A perceived lack of control could lead victims to rely more on emotion-focused strategies. A key advancement in research has been the development of cyberbullying-specific coping questionnaires. Although we have not the luxury of a wealth of evidence as to what methods and strategies are effective in terms of reducing and stopping victimization and reducing its effects, Dehue and co-authors state that we cannot afford to wait before providing guidance. For instance, seeking social support is an evidence-based recommendation for prevention and reduction of negative impact.

Furthermore, great emphasis is placed in this chapter on tailoring the advice appropriately for individual personality, outcome expectancies, and knowledge. In addition, there is a paucity of empirical evidence to support the effectiveness of programmes; a concern also highlighted by Seung-Ha Lee. Only a handful of programmes have a theoretical basis and have been assessed for effectiveness. Dehue and colleagues also recommend a particular focus on content as it is important to provide novel and helpful information whilst also being limited and not too complex. A possible approach mentioned is ‘gamification’ of an intervention. Along with content, structure must be appropriate with easy procedures, simple design and other helpful features to enhance convenience for the user.

Picking up on some of the points made by Francine Dehue, Trijntje Völlink, and Nicole Gunther regarding intervention, we (Corcoran and Mc Guckin) discussed some important considerations when exploring the issue of coping with cyberbullying. Our chapter begins by placing cyberbullying in a historical context and highlighting the fact that today’s youth is not the first generation to be exposed to new and frightening technologies, nor is it likely to be the last. Therefore we ask, is this not a challenge that requires us to use our existing coping skills, as opposed to developing new ones. It is also emphasised that the adolescents (on whom most research focuses) are those who are at a particularly vulnerable stage developmentally for victimization and ill-considered coping. This chapter highlights the importance of appraisal of actual or perceived victimization, as well as coping strategies employed. Echoing a point made by Dehue and co-authors, we emphasised that coping with victimization does not happen in a vacuum or as part of some template. Every incident and response comes with personal and situational factors which impact the development of the situation. Therefore, again aligning with Dehue and colleagues’ recommendations regarding tailoring of interventions, it is not ideal for researchers to offer generic advice regarding coping.

The methodological inconsistency highlighted throughout this book also pertains to studies on coping with traditional bullying and cyberbullying. This issue, in conjunction with the lack of focus on effectiveness of responses, leaves us with a lack of evidence to inform our guidance. Although insights have been gained in relation to coping effectively with traditional victimization, we question whether cyberbullying requires a different set of responses. Parental support or reluctance to seek it emerges as an important issue in the literature, whilst social support seeking generally may be dependent on gender. Technical responses; often considered

a potential quick fix, are helpful but not without limitations. Avoidant or distancing coping seems to be highly undesirable.

Taking coping to a school or community intervention level, this chapter also provides a review of an intervention programme which appears to meet the criteria of theory-based, methodologically sound, and empirically tested. Coping at an international level can be seen in funded projects such as the Cyber Training projects and The COST Action IS0801. Although many of these efforts are focused on education-based or policy-based coping, there is also a form of legislative coping; the focus of which is prosecution of those who perpetrate cyberbullying. In this chapter, we ultimately argue against such an approach as an “educate-first” philosophy is preferable.

Following this, Nicole Gunther, Francine Dehue, and Viviane Thewissen provide a valuable review of intervention efforts to prevent and counteract cyberbullying among youth and its negative effects on mental health, with a particular focus on Internet-based interventions. They comment on the common finding that research has indicated an association between victimization and stress, low self-esteem, anxiety, depression, and suicidal ideation. However, importantly, they note that some research has revealed that some negative states were in fact predictors of cyber victimization rather than consequences. Whilst all roles involved in cyberbullying are associated with negative states, it is the group who both perpetrate and are victimized who seem to have the worst mental health markers. Similar to previous chapters, Gunther and colleagues highlight the lack of evidence-supported interventions, and furthermore, they comment on the difficulty associated with parent-directed interventions, due to the lack of desire among young people to report to parents when victimized. Therefore, they argue that the Internet-based intervention is a logical alternative. They make reference to the implementation of e-mental health; Internet-based interventions aimed at supporting the mental well-being of the user. There are a number of potential advantages of e-mental health outlined, such as the avoidance of stigma and the potential to get help at any time and in any place (interestingly the same time and space characteristics that make cyberbullying so challenging). Overall, Gunther and colleagues suggest that there is growing support for the effectiveness of Internet-based treatment interventions which have a CBT basis and aim to reduce anxiety symptoms. However, they caution that more research is required, especially in relation to other disorders among children and adolescents. Difficulty for health professionals in detecting cyberbullying as a cause of mental health difficulties is one reason that Gunther and co-authors recommend facilitating online intervention. In addition, this chapter suggests that it would be of value to examine current effective e-mental health interventions and include some of their modules in a web-based programme for cyberbullied youth who also experience mental health difficulties, or alternatively, to include a cyberbullying-focused module in a Internet-based mental health intervention. Although the authors recognise that there are limitations to the current literature, they feel that there is promise in the online intervention approach, and advocate for blended care; a combination of cyber-based and face-to-face contact for those in need of support.

Somewhat straddling different sections of the book Marilyn Campbell provides the Australian perspective; with a chapter that covers fundamental issues associated with cyberbullying research, examines prevalence rates, associated variables, and efforts to counter cyberbullying. Similar to Dehue and co-authors and reiterating fundamental points made in previous chapters, Campbell proposes that the lack of consensus regarding a definition of cyberbullying hampers the development of appropriate measures, and this in turn negatively

affects the advancement of intervention efforts. Campbell comments on some of the key difficulties with regard to achieving a suitable definition and highlights the valuable work done by Australian researchers to further these efforts with much of the debate focusing on the elements of intent, repetition, and power imbalance. This chapter also discusses the examination of prevalence rates among not only school students, but also among college students and the workforce; an age group often neglected in the international literature. This chapter also reviews Australian research on the associated effects of involvement in cyberbullying, the motivations to perpetrate the behaviour, and the role of the bystanders; illustrating the importance of this knowledge to inform efforts to counter the problem.

Offering an interesting perspective on societal perceptions of cyberbullying, Campbell talks about the role of the media in terms of “agenda setting.” The ways in which the media frame cyberbullying can offer reassurance or can lead to moral panic. Campbell suggests that in Australia there is a tendency towards the latter. Such accounts of cyberbullying has had the result of calls for legislation to be developed to tackle the problem. Similar to the discussion proposed by Corcoran and Mc Guckin, Campbell advises caution in relation to criminalizing cyberbullying as it may not exactly have the desired impact. In 2015 actions were taken by the Federal government to provide cyber victimized Australian children with a complaints system. Valuable research has been conducted in Australia to assess the development and implementation of relevant school policy. Within policy development, debate regarding definitions rears its head again. Furthermore, it is evident that the differing characteristics of cyberbullying (e.g., always on nature of the Internet) pose challenges for schools. Campbell highlights the efforts by the Australian Federal government to combat cyberbullying; development of resources being one indication of this.

Although there have also been non-governmental resources allocated to tackle cyberbullying, the absence of evidence-based practice, led to the establishment of the Australian Universities’ Anti-bullying Research Alliance (AUARA) which received funding towards production of evidence-based outcomes to reduce negative effects of cyberbullying. These research projects include Cyber Friendly Schools, Beyond Bullying, research on legal interventions, and Safe and Well Project. Marilyn Campbell’s chapter goes a long way towards illustrating the layers and complexity of the cyberbullying issue. Furthermore, it reveals the divergent perspectives; the quick fix legislative approach desired by many is in stark contrast with the tailored, theory-based and evidence-based approach advocated by many such as Dehue, Völlink, and Gunther. It is heartening to see the collaborative and focused approach from the AUARA; a great example of putting (expert) heads together to advance knowledge and practice.

In the final chapter Caroline Wheeler examines teachers’ experiences of cyberbullying amongst students. Highlighting that aggression in school has long been a source of interest and concern, she highlights the more recent interest in cyberbullying specifically. Furthermore, the paucity of research on Irish teachers’ experiences with, and perceptions of, cyberbullying, has likely hampered efforts to intervene effectively. Wheeler acknowledges that efforts have been made to address bullying problems in a modern Irish context with formation of an Anti-Bullying Working Group and updating of guidelines. In her own study of Irish teachers, Wheeler found that cyberbullying is recognised as a problem at school, and that although only around half of teachers reported feeling confident in identifying and managing cyberbullying, the large majority said that they would do something if an incident came to their attention. Many teachers felt that their training had not prepared them for cyberbullying issues, but

expressed a desire for upskilling in this regard. Interestingly, the qualitative component of the research indicated that all teachers agreed that, compared with males, when female students cyberbully it is more malicious, intentional, and it is more frequent. This brings to mind the argument regarding gender stereotyping put forward by Navaro and colleagues earlier in the book. The qualitative data also raises the important issue of the parental role in cyberbullying; as some parents actually participate in or worsen the situation. There was also reference to the sharing of responsibility, so that teachers are not overburdened with cyberbullying problems. It is vital that teachers receive adequate training and support in addressing bullying problems among students.

CONCLUSION

As my colleague Conor Mc Guckin often warns, not only do we need to deal with the current cyber situation, we also need to be prepared for what is coming next. Something we should have learned by now is that technological advancement waits for no one. As soon as we have found our footing with the challenges of the most current technology, progress will knock us off balance. In this way, we need to be considerate of the knowledge we have garnered so far whilst keeping a vigilant eye on what is coming down the line. This book has provided food for thought and challenges us to consider the best way forward. A common theme among authors was the recommendation that we must begin to diversify our research methods as more longitudinal research and control trials can allow for conclusions to be drawn regarding cause and effect rather than correlation. Furthermore, the literature is weakened by the focus on quantitative methods; we need to hear the voice of youth when attempting to conceptualise cyberbullying, understand the lived experience, and intervene in a positive sense. Many of the authors have indicated the problematic nature of cyberbullying as a label and struggle to reach a consensus on the definition. Moreover, they have highlighted how this negatively impacts on measurement and development of instruments; an issue which in turn creates difficulty with assessing interventions. Whether researchers decide to forge ahead with the cyberbullying construct as an extension of traditional bullying, or view it as a distinct construct which requires a different label; this is a matter of fundamental importance if the field is to progress. Such a development would allow for comparable research to emerge through improved measurement techniques. Gender is a variable which has been referenced throughout the chapters; however, the chapter provided by Raúl Navarro and colleagues certainly challenges current thinking on this issue. We know that bias, be it cultural or gender-based, can cloud our perception of psychological and social issues, and so it is imperative that researchers and practitioners properly consider the possibility that we misjudge the role of gender in traditional bullying and cyberbullying. If nothing else, it is our duty to examine this further.

There is a need to consider also, the different theoretical and conceptual lenses that can be applied to cyberbullying. For instance, the argument for a positive psychological perspective creates opportunity to gain further insights into the nature of cyberbullying. Moreover, Stephen Minton makes a compelling argument for the consideration of the influence of physical and psychological distance as well as factors such as bystander apathy in relation to cyberbullying. Cross-national research not only offers international prevalence rates, it also provides insights regarding contextual and cultural factors which may influence cyberbullying and affect the

efficacy of interventions, and it highlights both the commonalities and uniqueness of human experience. Whilst South Korean research has many aspects of cyberbullying in common with other nations, Seung-Ha Lee also indicated unique forms of extortive behaviour which takes place online.

With respect to intervention it seems that we can best advance our efforts by tailoring the interventions to the individual, as a “one size fits all” approach does not often satisfy diverse personal characteristics and circumstances. Also, the message through these latter chapters is loud and clear; we need theory-informed, evidence-based practice in the future. Although legislation is an important consideration when examining the issue of cyberbullying, prosecuting cyberbullies may not be the best approach, particularly in light of the age group most vulnerable to involvement. Furthermore, change to legislation does not always keep pace with the developing technology and service providers tend to be global in nature as opposed to being confined to one specific territory. Education seems to be our best option currently, and it we are to successfully educate our young people to protect themselves and each other online, then we must support their teachers and parents to guide them. What is clear from the chapters reviewed here, is that there is a high level of agreement amongst the authors as to how we can best proceed. However, each chapter also offers a unique and thoughtful perspective.
